curate26_vp_furfural

tutorials/props/curation/curate26_vp_furfural

What it does: Antoine vapour pressure of furfural fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of furfural, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp furfural'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/acs.jced.7b00574 19 pts 326.05-415.15 K Zheng; Luo; Yin; Chen et al. 10.1021/je060406c 16 pts 276.7-323.4 K Emel'yanenko; Dabrowska; Verevkin; Hertel et al. 10.1021/je020117y 9 pts 339.16-429.5 K Fele; Grilc SET ASIDE BY NAME: 10.1016/j.fluid.2014.10.037: 3 pressure point(s), fewer than 5 10.1016/j.jct.2018.03.019: 1 pressure point(s), fewer than 5 10.1021/acs.jced.8b00451: 1 pressure point(s), fewer than 5 10.1021/je400885z: 4 pressure point(s), fewer than 5

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 434.85 K is judged against the range of the KEPT points (all studies span 276.7-429.5 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). curate27_vp_glycerol

tutorials/props/curation/curate27_vp_glycerol

What it does: Antoine vapour pressure of glycerol fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of glycerol, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp glycerol'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.fluid.2015.03.038 113 pts 303.59-436.13 K Verevkin; Zaitsau; Emel'yanenko; Zhabina 10.1021/je200766t 11 pts 351.8-462.86 K Mokbel; Sawaya; Zanota; Naccoul et al. 10.1016/j.jct.2012.09.032 5 pts 477.25-520.65 K Veneral; Benazzi; Mazutti; Voll et al. 10.1021/je800070y 5 pts 463.15-543.15 K Yan; Suppes SET ASIDE BY NAME: 10.1016/j.jct.2013.09.046: 4 pressure point(s), fewer than 5 10.1021/acs.jced.5b01080: 3 pressure point(s), fewer than 5

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 563.15 K is judged against the range of the KEPT points (all studies span 303.59-543.15 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). What it does: NRTL propanal-1Propanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair propanal 1Propanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. propanal (CAS 123-38-6, InChIKey NBBJYMSMWIIQGU-UHFFFAOYSA-N) + 1Propanol (CAS 71-23-8, InChIKey BDERNNFJNOPAEC-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

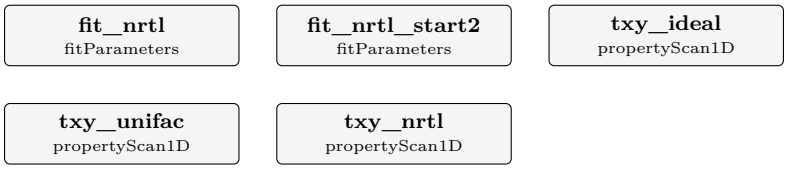
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je100912t block 9 24 pts 101.325 kPa 322.35-367.65 K U 0.22-0.26 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 24 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 267.8 K, b_ji = -272.6 K over 24 kept points of 1 laboratories (0 discarded): max |dT| 0.395 K, mean 0.225 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (267.8, -272.6). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Propanol-propanal.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.395 K over the 24 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je100912t); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate286_nrtl_ethylAcetate_nNonane

tutorials/props/curation/curate286_nrtl_ethylAcetate_nNonane

What it does: NRTL ethylAcetate-nNonane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair ethylAcetate nNonane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. ethylAcetate (CAS 141-78-6, InChIKey XEKOWRVHYACXOJ-UHFFFAOYSA-N) + nNonane (CAS 111-84-2, InChIKey BKIMMITUMNQMOS-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je100832h block 34 24 pts 101.32 kPa 350.70-420.00 K U 0.44-0.44 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 24 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 205.9 K, b_ji = 89.9 K over 24 kept points of 1 laboratories (0 discarded): max |dT| 0.651 K, mean 0.291 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (205.9, 89.9). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/ethylAcetate-nNonane.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.651 K over the 24 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je100832h); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate28_vp_methylDiEthanolAmine

tutorials/props/curation/curate28_vp_methylDiEthanolAmine

What it does: Antoine vapour pressure of methylDiEthanolAmine fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of methylDiEthanolAmine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp methylDiEthanolAmine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je060269j 9 pts 519.7-738.4 K VonNiederhausern; Wilson; Giles 10.1021/je400373d 7 pts 467.34-520.28 K Yang; Feng; Cheng; Zhang et al. 10.1021/je800290k 7 pts 409.69-435.5 K Kim; Svendsen; Borresen 10.1021/acs.jced.8b00054 6 pts 430.52-488.42 K Soames; Helal; Iglauer; Barifcani et al. SET ASIDE BY NAME: 10.1016/j.fluid.2010.08.026: j.fluid.2010.08.026.xml: 1 of 1 pressure rows of methylDiEthanolAmine declare no stated uncertainty – a partial uncertainty is no uncertainty for a held-out band. Nothing was written.

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 520.15 K is judged against the range of the KEPT points (all studies span 409.69-738.4 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). curate29_vp_methylTertPentylEther

tutorials/props/curation/curate29_vp_methylTertPentylEther

What it does: Antoine vapour pressure of methylTertPentylEther fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of methylTertPentylEther, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp methylTertPentylEther'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je101250d 21 pts 313.44-359.95 K Mejia; Segura; Cartes 10.1021/je0255980 11 pts 274.2-307.8 K Verevkin; Krasnykh; Vasiltsova; Heintz 10.1021/je049867t 11 pts 298.02-355.64 K Vorenberg; Raal; Ramjugernath 10.1021/je901026b 5 pts 318.13-338.28 K Bernatova; Pavlicek; Wichterle SET ASIDE BY NAME: 10.1016/j.fluid.2005.06.017: 1 pressure point(s), fewer than 5 10.1016/j.fluid.2005.10.024: 2 pressure point(s), fewer than 5 10.1021/je200215d: 1 pressure point(s), fewer than 5

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 359.51 K is judged against the range of the KEPT points (all studies span 274.2-359.95 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). curate301_nrtl_ethylFormate_nOctane

tutorials/props/curation/curate301_nrtl_ethylFormate_nOctane

What it does: NRTL ethylFormate-nOctane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair ethylFormate nOctane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. ethylFormate (CAS 109-94-4, InChIKey WBJINCZRORDGAQ-UHFFFAOYSA-N) + nOctane (CAS 111-65-9, InChIKey TVMXDCGIABBOFY-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2015.05.031 block 46 22 pts 101.32 kPa 327.55-393.02 K U 0.14-2.12 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 22 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 513.5 K, b_ji = -13.8 K over 22 kept points of 1 laboratories (0 discarded): max |dT| 0.594 K, mean 0.270 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (513.5, -13.8). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/ethylFormate-nOctane.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.594 K over the 22 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2015.05.031); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate306_nrtl_methanol_2Methyl1Butanol

tutorials/props/curation/curate306_nrtl_methanol_2Methyl1Butanol

What it does: NRTL methanol-2Methyl1Butanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair methanol 2Methyl1Butanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methanol (CAS 67-56-1, InChIKey OKKJLVBELUTLKV-UHFFFAOYSA-N) + 2Methyl1Butanol (CAS 137-32-6, InChIKey QPRQEDXDYOZYLA-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je0500330 block 14 21 pts 101.3 kPa 338.23-398.75 K U 0.33-2.1 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 21 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 249.2 K, b_ji = -175.1 K over 21 kept points of 1 laboratories (0 discarded): max |dT| 0.808 K, mean 0.269 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (249.2, -175.1). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/2Methyl1Butanol-methanol.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.808 K over the 21 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je0500330); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate30_vp_methylethanolamine

tutorials/props/curation/curate30_vp_methylethanolamine

What it does: Antoine vapour pressure of methylethanolamine fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of methylethanolamine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp methylethanolamine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je049761y 16 pts 274.9-320.2 K Kapteina; Slovik; Verevkin; Heintz 10.1021/je101259r 16 pts 341.8-451.1 K Klepacova; Huttenhuis; Derks; Versteeg 10.1021/je400373d 7 pts 388-431.2 K Yang; Feng; Cheng; Zhang et al. SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 432.388 K is judged against the range of the KEPT points (all studies span 274.9-451.1 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Antoine log10(Psat/bar) = 5.008624 - 1878.4613/(T + -62.8829), in-sample R2 0.999948 over 16 points, 274.9-320.2 K. HELD OUT: 16 points, AAD 15.8476 % against the band 2.6 % → notValidated. Its own normal boiling point (101.325 kPa): 438.36 K. NOT PROMOTED: held-out verdict notValidated (AAD 15.85 % against the band 2.6 % declared before the fit); the record keeps AmbroseWalton THEN C281 step 3, objective twoStage, one study fitted and one held out, judged by the band (superseded by C283): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). curate310_nrtl_vinylAcetate_cumene

tutorials/props/curation/curate310_nrtl_vinylAcetate_cumene

What it does: NRTL vinylAcetate-cumene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair vinylAcetate cumene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. vinylAcetate (CAS 108-05-4, InChIKey XTXRWKRVRITETP-UHFFFAOYSA-N) + cumene (CAS 98-82-8, InChIKey RWGFKTVRMDUZSP-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je7004402 block 8 23 pts 97.3 kPa 345.46-421.85 K U 0.68-0.71 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 23 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

curate314_nrtl_1Propanol_dimethylSulfoxide

tutorials/props/curation/curate314_nrtl_1Propanol_dimethylSulfoxide

What it does: NRTL 1Propanol-dimethylSulfoxide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 1Propanol dimethylSulfoxide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 1Propanol (CAS 71-23-8, InChIKey BDERNNFJNOPAEC-UHFFFAOYSA-N) + dimethylSulfoxide (CAS 67-68-5, InChIKey IAZDPXIOMUYVGZ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je100033s block 13 22 pts 101.3 kPa 371.51-458.68 K U 0.2-0.88 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 22 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -469.4 K, b_ji = 358.9 K over 22 kept points of 1 laboratories (0 discarded): max |dT| 1.152 K, mean 0.378 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on A DIFFERENT pair (1334.5, -762.8). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Propanol-dimethylSulfoxide.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.152 K over the 22 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je100033s); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate31_vp_monoethanolamine

tutorials/props/curation/curate31_vp_monoethanolamine

What it does: Antoine vapour pressure of monoethanolamine fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of monoethanolamine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp monoethanolamine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.fluid.2015.06.045 38 pts 273.65-303.16 K Ruzicka; Fulem; Mahnel; Cervinka 10.1021/je800530u 26 pts 283.15-363.15 K Belabbaci; Razzouk; Mokbel; Jose et al. 10.1021/je800290k 16 pts 357.46-435.61 K Kim; Svendsen; Borresen 10.1021/je049761y 13 pts 279-324.5 K Kapteina; Slovik; Verevkin; Heintz 10.1021/je101259r 7 pts 358.6-441.9 K Klepacova; Huttenhuis; Derks; Versteeg 10.1021/je400885z 6 pts 373.15-423.15 K McDougal; Jasperson; Wilson SET ASIDE BY NAME: 10.1021/je3002078: 1 pressure point(s), fewer than 5 10.1021/je7001336: 1 pressure point(s), fewer than 5

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 444.15 K is judged against the range of the KEPT points (all studies span 273.65-441.9 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Antoine log10(Psat/bar) = 6.766025 - 2807.2440/(T + -17.4236), in-sample R2 0.999993 over 38 points, 273.65-303.16 K. HELD OUT: 26 points, AAD 2.8176 % against the band 5.4 % → validated. Its own normal boiling point (101.325 kPa): 432.68 K. NOT PROMOTED: validated, but the fitted Antoine's normal boiling point 432.68 K misses the record's Tb 444.15 K by -11.47 K, outside the declared 2 K – an extrapolation that contradicts the record; the record keeps AmbroseWalton THEN C281 step 3, objective twoStage, one study fitted and one held out, judged by the band (superseded by C283): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 6.301246 - 2556.1410/(T + -30.0521), in-sample R2 0.999986 over 38 points, 273.65-303.16 K. curate321_nrtl_diEthylCarbonate_ethylBenzene

tutorials/props/curation/curate321_nrtl_diEthylCarbonate_ethylBenzene

What it does: NRTL diEthylCarbonate-ethylBenzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair diEthylCarbonate ethylBenzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. diEthylCarbonate (CAS 105-58-8, InChIKey OIFBSDVPJOWBCH-UHFFFAOYSA-N) + ethylBenzene (CAS 100-41-4, InChIKey YNQLUTRBYVCPMQ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/acs.jced.6b00085 block 10 20 pts 101.33 kPa 399.86-409.10 K U 0.41-0.41 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 20 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

curate326_nrtl_ethanol_methylcyclohexane

tutorials/props/curation/curate326_nrtl_ethanol_methylcyclohexane

What it does: NRTL ethanol-methylcyclohexane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair ethanol methylcyclohexane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. ethanol (CAS 64-17-5, InChIKey LFQSCWFLJHTTHZ-UHFFFAOYSA-N) + methylcyclohexane (CAS 108-87-2, InChIKey UAEPNZWRGJTJPN-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je0342318 block 9 22 pts 101.3 kPa 345.30-368.84 K U 0.68-1.3 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 22 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 242.6 K, b_ji = 701.0 K over 22 kept points of 1 laboratories (0 discarded): max |dT| 1.128 K, mean 0.658 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (242.6, 701.0). NOT PROMOTABLE (fit grade warning, max |dT| 1.128 K): the pair splits ONE liquid inside its own validity span (check_regressed_pairs arm f) – predicts a LIQUID-LIQUID SPLIT at 345.30 K (x_ethanol 0.199 .. 0.538), inside its own validity span 345.3-368.84 K – its evidence is bubble temperatures of ONE liquid, which a bubble scan cannot contradict; a pair that splits that liquid stays in its case, not the catalogue (or it DECLARES 'liquidLiquid true;' with tie-line evidence and a gap band) – it rests on ONE laboratory's measurements (doi 10.1021/je0342318); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate32_vp_nEicosane

tutorials/props/curation/curate32_vp_nEicosane

What it does: Antoine vapour pressure of nEicosane fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of nEicosane, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp nEicosane'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/acs.jced.6b00821 8 pts 313.15-343.15 K Widegren; Beall; Tolbert; Lovestead et al. 10.1021/je800534x 6 pts 312.76-373.17 K Razzouk; Naccoul; Mokbel; Saab et al. SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 616.95 K is judged against the range of the KEPT points (all studies span 312.76-373.17 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

curate333_nrtl_monochlorobenzene_nNDimethylformamide

tutorials/props/curation/curate333_nrtl_monochlorobenzene_nNDimethylformamide

What it does: NRTL monochlorobenzene-nNDimethylformamide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair monochlorobenzene nNDimethylformamide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. monochlorobenzene (CAS 108-90-7, InChIKey MVPPADPHJFYWMZ-UHFFFAOYSA-N) + nNDimethylformamide (CAS 68-12-2, InChIKey ZMXDDKWLCZADIW-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2008.07.018 block 21 20 pts 95.5 kPa 402.85-416.15 K U 0.69-0.69 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 20 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -86.6 K, b_ji = 475.0 K over 20 kept points of 1 laboratories (0 discarded): max |dT| 0.222 K, mean 0.135 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (-86.6, 475.0). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/monochlorobenzene-nNDimethylformamide.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.222 K over the 20 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2008.07.018); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate33_vp_nHexylAcetate

tutorials/props/curation/curate33_vp_nHexylAcetate

What it does: Antoine vapour pressure of nHexylAcetate fitted by the curation pipeline to measured vapour pressures (ThermoML locates, the article sources), held out against an independent study

The story: the vapour pressure of nHexylAcetate, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp nHexylAcetate'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je050141m 14 pts 397.97-439.98 K Schmitt; Hasse 10.1016/j.jct.2005.08.003 13 pts 274.5-309.1 K Krasnykh; Verevkin; Koutek; Doubsky SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 444.65 K is judged against the range of the KEPT points (all studies span 274.5-439.98 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C281 step 2, objective leastSquares (log10 P), the same partition and band: WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). curate341_nrtl_1Hexene_diEthylCarbonate

tutorials/props/curation/curate341_nrtl_1Hexene_diEthylCarbonate

What it does: NRTL 1Hexene-diEthylCarbonate regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 1Hexene diEthylCarbonate (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 1Hexene (CAS 592-41-6, InChIKey LIKMAJRDDDTEIG-UHFFFAOYSA-N) + diEthyl-Carbonate (CAS 105-58-8, InChIKey OIFBSDVPJOWBCH-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

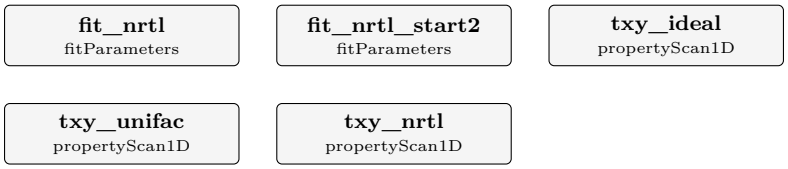
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/acs.jced.6b00905 block 8 21 pts 100 kPa 336.87-393.64 K U 0.24-2.03 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 21 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 262.2 K, b_ji = -34.3 K over 21 kept points of 1 laboratories (0 discarded): max |dT| 0.690 K, mean 0.157 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (262.2, -34.3). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Hexene-diEthylCarbonate.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.690 K over the 21 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/acs.jced.6b00905); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate346_nrtl_acetone_224Trimethylpentane

tutorials/props/curation/curate346_nrtl_acetone_224Trimethylpentane

What it does: NRTL acetone-224Trimethylpentane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair acetone 224Trimethylpentane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. acetone (CAS 67-64-1, InChIKey CSCPPACGZOOCGX-UHFFFAOYSA-N) + 224Trimethylpentane (CAS 540-84-1, InChIKey NHTMVDHEPJAVLT-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

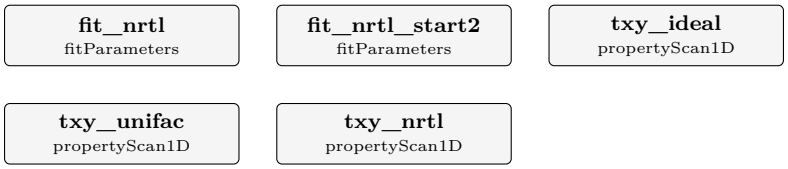
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2005.01.007 block 11 19 pts 101.32 kPa 328.74-364.14 K U 0.16-1.59 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 19 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 512.0 K, b_ji = 106.5 K over 19 kept points of 1 laboratories (0 discarded): max |dT| 0.693 K, mean 0.187 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (512.0, 106.5). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/224Trimethylpentane-acetone.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.693 K over the 19 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2005.01.007); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate34_vp_diethanolamine

tutorials/props/curation/curate34_vp_diethanolamine

What it does: Antoine vapour pressure of diethanolamine fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of diethanolamine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp diethanolamine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je101259r 5 pts 427.5-452.4 K Klepacova; Huttenhuis; Derks; Versteeg SET ASIDE BY NAME: 10.1016/j.jct.2018.09.002: 1 pressure point(s), fewer than 5

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 542 K is judged against the range of the KEPT points (all studies span 427.5-452.4 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 4.246563 - 1576.6883/(T + -168.4642), in-sample R2 0.999956 over 5 kept points, 427.5-452.4 K (10.1021/je101259r 5/5 kept). Relative error in P over the kept points: mean 0.2724 %, max 0.3326 %; AmbroseWalton on the same points: mean 15.9429 %, max 16.5744 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 540.25 K. curate350_nrtl_ethylAcetate_2Methyl1Propanol

tutorials/props/curation/curate350_nrtl_ethylAcetate_2Methyl1Propanol

What it does: NRTL ethylAcetate-2Methyl1Propanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair ethylAcetate 2Methyl1Propanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. ethylAcetate (CAS 141-78-6, InChIKey XEKOWRVHYACXOJ-UHFFFAOYSA-N) + 2Methyl1Propanol (CAS 78-83-1, InChIKey ZXEKIIBDNHEJCQ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je050420+ block 12 21 pts 101 kPa 352.20-379.96 K U 0.32-0.34 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 21 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. cyclohexane (CAS 110-82-7, InChIKey XDTMQSROBMDMFD-UHFFFAOYSA-N) + methylIsobutylKetone (CAS 108-10-1, InChIKey NTIZESTWPVYFNL-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je100776x block 9 21 pts 100 kPa 353.41-386.18 K U 0.17-0.26 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 21 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 380.7 K, b_ji = -53.9 K over 21 kept points of 1 laboratories (0 discarded): max |dT| 0.640 K, mean 0.285 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (380.7, -53.9). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/cyclohexane-methylIsobutylKetone.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.640 K over the 21 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je100776x); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate35_vp_mNitrotoluene

tutorials/props/curation/curate35_vp_mNitrotoluene

fit_antoine
vaporPressureFit

What it does: Antoine vapour pressure of mNitrotoluene fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of mNitrotoluene, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp mNitrotoluene'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.jct.2017.03.029 34 pts 290.6-338 K Bikelyte; Hartel; Stierstorfer; Klapotke et al. SET ASIDE BY NAME: 10.1021/je900293j: 3 pressure point(s), fewer than 5

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 504 K is judged against the range of the KEPT points (all studies span 290.6-338 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 6.592207 - 3238.6044/(T + 9.9450), in-sample R2 0.999449 over 34 kept points, 290.6-338 K (10.1016/j.jct.2017.03.029 34/34 kept). Relative error in P over the kept points: mean 1.6175 %, max 2.9342 %; AmbroseWalton on the same points: mean 48.1334 %, max 57.8067 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 481.76 K. NOT PROMOTED by the DEFAULT acceptance of DEV.md 4c C283 (no system/curationDict): 1 studies, 34 points kept, 0 discarded as outliers; max relative error 2.934 % (mean 1.617 %) against 5 % passes, but Tb lies outside the kept points' range and the normal boiling point 481.76 K, -22.24 K from the record's Tb 504 K is not within 1 K – the gap is announced; AmbroseWalton on the same points mean 48.13 % / max 57.81 %; the record keeps AmbroseWalton @@EARLIER-END@@

NO MEASURED POINT IS IN THIS TREE: constant/archiveDatasets declares every series by DOI, NIST URL and sha256; 'bin/choupo-curate fetch' regenerates them into constant/archiveExtracts/ (gitignored).

curate363_nrtl_vinylAcetate_diEthylCarbonate

tutorials/props/curation/curate363_nrtl_vinylAcetate_diEthylCarbonate

What it does: NRTL vinylAcetate-diEthylCarbonate regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair vinylAcetate diEthylCarbonate (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. vinylAcetate (CAS 108-05-4, InChIKey XTXRWKRVRITETP-UHFFFAOYSA-N) + diEthylCarbonate (CAS 105-58-8, InChIKey OIFBSDVPJOWBCH-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je049544x block 19 19 pts 101.3 kPa 347.20-395.50 K U 0.7-0.8 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

curate36_vp_nAminoethylEthanolamine

tutorials/props/curation/curate36_vp_nAminoethylEthanolamine

What it does: Antoine vapour pressure of nAminoethylEthanolamine fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of nAminoethylEthanolamine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp nAminoethylEthanolamine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je2002489 33 pts 323.2-374.2 K Verevkin; Tong; Welz-Biermann; Chernyak SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 517 K is judged against the range of the KEPT points (all studies span 323.2-374.2 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 6.274747 - 3062.5355/(T + -30.3642), in-sample R2 0.999411 over 33 kept points, 323.2-374.2 K (10.1021/je2002489 33/33 kept). Relative error in P over the kept points: mean 2.2635 %, max 4.4704 %; AmbroseWalton on the same points: mean 68.6798 %, max 79.7274 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 518.88 K. NOT PROMOTED by the DEFAULT acceptance of DEV.md 4c C283 (no system/curationDict): 1 studies, 33 points kept, 0 discarded as outliers; max relative error 4.47 % (mean 2.264 %) against 5 % passes, but Tb lies outside the kept points' range and the normal boiling point 518.88 K, +1.88 K from the record's Tb 517 K is not within 1 K – the gap is announced; AmbroseWalton on the same points mean 68.68 % / max 79.73 %; the record keeps AmbroseWalton @@EARLIER-END@@

NO MEASURED POINT IS IN THIS TREE: constant/archiveDatasets declares every series by DOI, NIST URL and sha256; ‘bin/choupo-curate fetch‘ regenerates them into constant/archiveExtracts/ (gitignored).

RESULT @@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in ‘expected‘; measured, not argued). Objective twoStage. curate371_nrtl_methylFormate_mXylene

tutorials/props/curation/curate371_nrtl_methylFormate_mXylene

What it does: NRTL methylFormate-mXylene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair methylFormate mXylene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methylFormate (CAS 107-31-3, InChIKey TZIHFWKZFHZASV-UHFFFAOYSA-N) + mXylene (CAS 108-38-3, InChIKey IVSZLXZYQVIEFR-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je200974r block 17 21 pts 101.33 kPa 305.66-411.07 K U 0.23-1.78 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

curate376_nrtl_trichloroethylene_nNDimethylformamide

tutorials/props/curation/curate376_nrtl_trichloroethylene_nNDimethylformamide

What it does: NRTL trichloroethylene-nNDimethylformamide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair trichloroethylene nNDimethylformamide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. trichloroethylene (CAS 79-01-6, InChIKey XSTXAVWGXDQKEL-UHFFFAOYSA-N) + nNDimethylformamide (CAS 68-12-2, InChIKey ZMXDDKWLCZADIW-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2006.08.018 block 29 19 pts 95.5 kPa 359.15-407.85 K U 0.69-0.69 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

curate37_vp_nAminoethylPiperazine

tutorials/props/curation/curate37_vp_nAminoethylPiperazine

What it does: Antoine vapour pressure of nAminoethylPiperazine fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of nAminoethylPiperazine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp nAminoethylPiperazine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.jct.2009.09.003 22 pts 295.7-338.1 K Efimova; Emel'yanenko; Verevkin; Chernyak SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 495.15 K is judged against the range of the KEPT points (all studies span 295.7-338.1 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 6.171252 - 2614.8819/(T + -43.5764), in-sample R2 0.999615 over 22 kept points, 295.7-338.1 K (10.1016/j.jct.2009.09.003 22/22 kept). Relative error in P over the kept points: mean 1.7273 %, max 3.6564 %; AmbroseWalton on the same points: mean 14.4097 %, max 20.8514 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 467.69 K. NOT PROMOTED by the DEFAULT acceptance of DEV.md 4c C283 (no system/curationDict): 1 studies, 22 points kept, 0 discarded as outliers; max relative error 3.656 % (mean 1.727 %) against 5 % passes, but Tb lies outside the kept points' range and the normal boiling point 467.69 K, -27.46 K from the record's Tb 495.15 K is not within 1 K – the gap is announced; AmbroseWalton on the same points mean 14.41 % / max 20.85 %; the record keeps AmbroseWalton @@EARLIER-END@@

NO MEASURED POINT IS IN THIS TREE: constant/archiveDatasets declares every series by DOI, NIST URL and sha256; 'bin/choupo-curate fetch' regenerates them into constant/archiveExtracts/ (gitignored).

curate380_nrtl_2Methyl2Propanol_monochlorobenzene

tutorials/props/curation/curate380_nrtl_2Methyl2Propanol_monochlorobenzene

What it does: NRTL 2Methyl2Propanol-monochlorobenzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 2Methyl2Propanol monochlorobenzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 2Methyl2Propanol (CAS 75-65-0, InChIKey DKGAVHZHDRPRBM-UHFFFAOYSA-N) + monochlorobenzene (CAS 108-90-7, InChIKey MVPPADPHJFYWMZ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

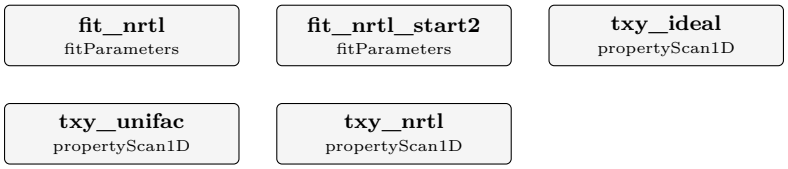
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/acs.jced.7b01021 block 3 18 pts 101.33 kPa 356.50-402.05 K U 0.18-2.94 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 18 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 394.6 K, b_ji = 23.2 K over 18 kept points of 1 laboratories (0 discarded): max |dT| 1.620 K, mean 0.435 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (394.6, 23.2). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/2Methyl2Propanol-monochlorobenzene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.620 K over the 18 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/acs.jced.7b01021); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate384_nrtl_isopropylAcetate_dimethylSulfoxide

tutorials/props/curation/curate384_nrtl_isopropylAcetate_dimethylSulfoxide

What it does: NRTL isopropylAcetate-dimethylSulfoxide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair isopropylAcetate dimethylSulfoxide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. isopropylAcetate (CAS 108-21-4, InChIKey JMMWKPVZQRWMSS-UHFFFAOYSA-N) + dimethylSulfoxide (CAS 67-68-5, InChIKey IAZDPXIOMUYVGZ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/acs.jced.6b00040 block 5 18 pts 101.3 kPa 363.59-456.01 K U 0.25-5.81 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ 1 point(s) of 18: doi 10.1021/acs.jced.6b00040 row 2: x 0.0266, P 101.300 kPa, T 444.02 K, dT -3.49 K @@OUTLIERS-END@@

curate38_vp_nPentylAcetate

tutorials/props/curation/curate38_vp_nPentylAcetate

What it does: Antoine vapour pressure of nPentylAcetate fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of nPentylAcetate, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp nPentylAcetate'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

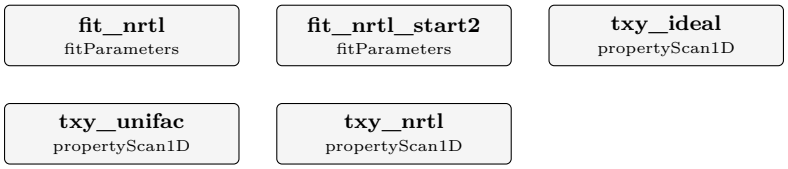
STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.fluid.2012.08.003 15 pts 274.2-313.4 K Samarov; Nazmutdinov; Verevkin SET ASIDE BY NAME: 10.1021/acs.jced.9b00068: 1 pressure point(s), fewer than 5 10.1021/je0301850: 3 pressure point(s), fewer than 5 10.1021/je101301s: 4 pressure point(s), fewer than 5 10.1021/je900812v: je900812v.xml: 1 of 1 pressure rows of nPentylAcetate declare no stated uncertainty – a partial uncertainty is no uncertainty for a held-out band. Nothing was written.

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 422.15 K is judged against the range of the KEPT points (all studies span 274.2-313.4 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 7.284960 - 3220.3538/(T + 36.8556), in-sample R2 0.999934 over 15 kept points, 274.2-313.4 K (10.1016/j.fluid.2012.08.003 15/15 kept). Relative error in P over the kept points: mean 0.6998 %, max 1.0682 %; AmbroseWalton on the same points: mean 35.9095 %, max 42.0745 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 405.55 K. NOT PROMOTED by the DEFAULT acceptance of DEV.md 4c C283 (no system/curationDict): 1 studies, 15 points kept, 0 discarded as outliers; max relative error 1.068 % (mean 0.6998 %) against 5 % passes, but Tb lies outside the kept points' range and the normal boiling point 405.55 K, -16.60 K from the record's Tb 422.15 K is not within 1 K – the gap is announced; AmbroseWalton on the same points mean 35.91 % / max 42.07 %; the record keeps AmbroseWalton @@EARLIER-END@@

NO MEASURED POINT IS IN THIS TREE: constant/archiveDatasets declares every series by DOI, NIST URL and sha256; ‘bin/choupo-curate fetch‘ regenerates them into constant/archiveExtracts/ (gitignored).



RESULT @@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in ‘expected‘; measured, not argued). Objective twoStage. curate392_nrtl_diisopropylEther_1Propanol

tutorials/props/curation/curate392_nrtl_diisopropylEther_1Propanol

What it does: NRTL diisopropylEther-1Propanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair diisopropylEther 1Propanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. diisopropylEther (CAS 108-20-3, InChIKey ZAFNJMIOTHYJRJ-UHFFFAOYSA-N) + 1Propanol (CAS 71-23-8, InChIKey BDERNNFJNOPAEC-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je900274n block 19 19 pts 101.32 kPa 341.86-364.78 K U 0.26-0.42 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 19 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 348.1 K, b_ji = 48.7 K over 19 kept points of 1 laboratories (0 discarded): max |dT| 0.165 K, mean 0.080 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (348.1, 48.7). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Propanol-diisopropylEther.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.165 K over the 19 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je900274n); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate397_nrtl_nPropylAcetate_2Methyl1Butanol

tutorials/props/curation/curate397_nrtl_nPropylAcetate_2Methyl1Butanol

What it does: NRTL nPropylAcetate-2Methyl1Butanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair nPropylAcetate 2Methyl1Butanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. nPropylAcetate (CAS 109-60-4, InChIKey YKYONYBAUNKHLG-UHFFFAOYSA-N) + 2Methyl1Butanol (CAS 137-32-6, InChIKey QPRQEDXDYOZYLA-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je500331g block 0 19 pts 101.3 kPa 376.85-401.15 K U 0.34-0.35 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

curate39_vp_phenanthrene

tutorials/props/curation/curate39_vp_phenanthrene

What it does: Antoine vapour pressure of phenanthrene fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of phenanthrene, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp phenanthrene'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.jct.2014.07.006 68 pts 400-480 K Ximello; Flores; Rojas; Camarillo et al. 10.1016/j.tca.2016.03.013 10 pts 384-420 K Sanchez-Bulas; Cruz-Vasquez; Hernandez-Obregon; Rojas SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 610.03 K is judged against the range of the KEPT points (all studies span 384-480 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). What it does: NRTL acetonitrile-ethyleneGlycol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair acetonitrile ethyleneGlycol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. acetonitrile (CAS 75-05-8, InChIKey WEVYAHXRMPXWCK-UHFFFAOYSA-N) + ethyleneGlycol (CAS 107-21-1, InChIKey LYCAIKOWRPUZTN-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

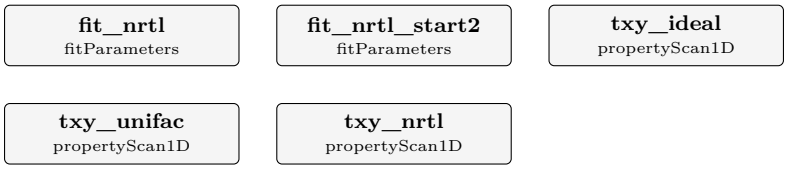
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2013.08.011 block 11 19 pts 101.3 kPa 354.95-457.27 K U 0.29-3.5 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 19 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 1.5 K, b_ji = 4.3 K over 19 kept points of 1 laboratories (0 discarded): max |dT| 0.573 K, mean 0.203 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on A DIFFERENT pair (505.8, -368.6). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/acetonitrile-ethyleneGlycol.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.573 K over the 19 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.jct.2013.08.011); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate405_nrtl_diethylSulfide_toluene

tutorials/props/curation/curate405_nrtl_diethylSulfide_toluene

What it does: NRTL diethylSulfide-toluene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair diethylSulfide toluene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. diethylSulfide (CAS 352-93-2, InChIKey LJSQFQKUNVCTIA-UHFFFAOYSA-N) + toluene (CAS 108-88-3, InChIKey YXFVVABEGXRONW-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je060093l block 9 17 pts 90.03 kPa 361.56-379.20 K U 0.17-0.2 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 17 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 83.7 K, b_ji = -82.7 K over 17 kept points of 1 laboratories (0 discarded): max |dT| 0.173 K, mean 0.091 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (83.7, -82.7). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/diethylSulfide-toluene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.173 K over the 17 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je060093l); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate40_vp_pyrene

tutorials/props/curation/curate40_vp_pyrene

What it does: Antoine vapour pressure of pyrene fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of pyrene, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp pyrene'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je800300x 23 pts 298.15-510 K Hanshaw; Nutt; Chickos SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 667.95 K is judged against the range of the KEPT points (all studies span 298.15-510 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 4.304067 - 2443.8287/(T + -91.2424), in-sample R2 0.999964 over 23 kept points, 298.15-510 K (10.1021/je800300x 23/23 kept). Relative error in P over the kept points: mean 2.3269 %, max 3.5140 %; AmbroseWalton on the same points: mean 49.2860 %, max 59.8483 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 659.79 K. NOT PROMOTED by the DEFAULT acceptance of DEV.md 4c C283 (no system/curationDict): 1 studies, 23 points kept, 0 discarded as outliers; max relative error 3.514 % (mean 2.327 %) against 5 % passes, but Tb lies outside the kept points' range and the normal boiling point 659.79 K, -8.16 K from the record's Tb 667.95 K is not within 1 K – the gap is announced; AmbroseWalton on the same points mean 49.29 % / max 59.85 %; the record keeps AmbroseWalton @@EARLIER-END@@

NO MEASURED POINT IS IN THIS TREE: constant/archiveDatasets declares every series by DOI, NIST URL and sha256; 'bin/choupo-curate fetch' regenerates them into constant/archiveExtracts/ (gitignored).

tutorials/props/curation/curate418_nrtl_methylFormate_pXylene

What it does: NRTL methylFormate-pXylene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair methylFormate pXylene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methylFormate (CAS 107-31-3, InChIKey TZIHFWKZFHZASV-UHFFFAOYSA-N) + pXylene (CAS 106-42-3, InChIKey URLKBWYHVLBVBO-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je200974r block 19 18 pts 101.33 kPa 306.10-402.18 K U 0.23-2.98 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

curate41_vp_squalane

tutorials/props/curation/curate41_vp_squalane

What it does: Antoine vapour pressure of squalane fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of squalane, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp squalane'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.jct.2019.03.032 32 pts 298.15-686.4 K Zafar; Chickos SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 623.15 K is judged against the range of the KEPT points (all studies span 298.15-686.4 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 5.524774 - 3196.0462/(T + -103.1706), in-sample R2 0.999906 over 32 kept points, 298.15-686.4 K (10.1016/j.jct.2019.03.032 32/32 kept). Relative error in P over the kept points: mean 5.4320 %, max 9.4322 %; AmbroseWalton on the same points: mean 69.1733 %, max 446.1594 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 682.26 K. NOT PROMOTED by the DEFAULT acceptance of DEV.md 4c C283 (no system/curationDict): 1 studies, 32 points kept, 0 discarded as outliers; max relative error 9.432 % (mean 5.432 %) against 5 %; AmbroseWalton on the same points mean 69.17 % / max 446.2 %; the record keeps AmbroseWalton @@EARLIER-END@@

curate42_vp_triethanolamine

tutorials/props/curation/curate42_vp_triethanolamine

What it does: Antoine vapour pressure of triethanolamine fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of triethanolamine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp triethanolamine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1016/j.tca.2018.05.007 55 pts 365-515 K Zghal; Farjas; Camps; Dammak et al. SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 613 K is judged against the range of the KEPT points (all studies span 365-515 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 6.379786 - 3486.4829/(T + -59.3907), in-sample R2 0.999017 over 54 kept points, 365-515 K (10.1016/j.tca.2018.05.007 54/55 kept). Relative error in P over the kept points: mean 4.8557 %, max 12.1496 %; AmbroseWalton on the same points: mean 49.4296 %, max 83.3204 %. curate430_nrtl_methylIsobutylKetone_nNDimethylacetamide

tutorials/props/curation/curate430_nrtl_methylIsobutylKetone_nNDimethylacetamide

What it does: NRTL methylIsobutylKetone-nNDimethylacetamide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair methylIsobutylKetone nNDimethylacetamide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methylIsobutylKetone (CAS 108-10-1, InChIKey NTIZESTWPVYFNL-UHFFFAOYSA-N) + nNDimethylacetamide (CAS 127-19-5, InChIKey FXHOOIRPVKKKFG-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/acs.jced.9b00535 block 5 16 pts 101.3 kPa 391.30-436.45 K U 0.61-0.62 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 16 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

What it does: NRTL mEthyltoluene-124Trimethylbenzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair mEthyltoluene 124Trimethylbenzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. mEthyltoluene (CAS 620-14-4, InChIKey ZLCSFXXPPANWQY-UHFFFAOYSA-N) + 124Trimethylbenzene (CAS 95-63-6, InChIKey GWHJZXXIDMPWGX-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

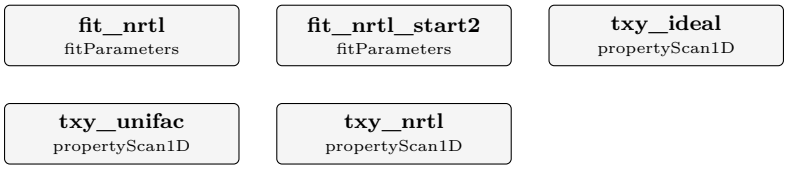
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2013.01.016 block 9 14 pts 20 kPa 380.93-387.52 K U 0.12-0.12 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 14 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -203.2 K, b_ji = 187.0 K over 14 kept points of 1 laboratories (0 discarded): max |dT| 0.432 K, mean 0.264 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on A DIFFERENT pair (746.5, -484.2). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/124Trimethylbenzene-mEthyltoluene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.432 K over the 14 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.jct.2013.01.016); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate439_nrtl_nNDimethylformamide_1Hexanol

tutorials/props/curation/curate439_nrtl_nNDimethylformamide_1Hexanol

What it does: NRTL nNDimethylformamide-1Hexanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair nNDimethylformamide 1Hexanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. nNDimethylformamide (CAS 68-12-2, InChIKey ZMXDDKWLCZADIW-UHFFFAOYSA-N) + 1Hexanol (CAS 111-27-3, InChIKey ZSIAUFGUXNUGDI-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2010.08.010 block 12 14 pts 95.6 kPa 421.34-427.65 K U 0.44-0.45 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 14 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 897.1 K, b_ji = -443.0 K over 14 kept points of 1 laboratories (0 discarded): max |dT| 0.766 K, mean 0.462 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (897.1, -443.0). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Hexanol-nNDimethylformamide.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.766 K over the 14 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2010.08.010); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate43_vp_triethylamine

tutorials/props/curation/curate43_vp_triethylamine

What it does: Antoine vapour pressure of triethylamine fitted by the curation pipeline to the measured vapour pressures of every usable laboratory (ThermoML locates, the articles source), outliers discarded by name

The story: the vapour pressure of triethylamine, REFITTED to measurements (DEV.md 4c C281 and C283). Written by 'bin/choupo-curate vp triethylamine'; everything above the RESULT paragraph is the DECLARATION, committed before any fit ran, so it can be read against the result.

WHY. The catalogue record carried 'vaporPressure { model AmbroseWalton; }', a corresponding-states ESTIMATE from Tc, Pc and omega that never reads the record's own Tb (C279 measured a median 19.6 % AAD over the 25 such records with archive data). Here a three-parameter Antoine is fitted to EVERY usable laboratory's measurements of it.

STUDIES (one per article, extracted by 'choupo-thermoml extract-vp'; ranked by points, ties by DOI): 10.1021/je800603z 5 pts 273.04-352.77 K Mokbel; Razzouk; Sawaya; Jose SET ASIDE BY NAME: (none)

FIT AND GRADED ACCEPTANCE (DEV.md 4c C285, Vitor 2026-11-10; the evidence, objective and outliers of C283; declared before the fit). EVIDENCE: every study above is fitted; none is held out (C283 amended: laboratories disagree with each other by more than they claim, so the test is agreement across all of them, not one laboratory's claimed precision). OBJECTIVE: 'objective { method twoStage; }' – least squares in log10 P for a first estimate, then the LARGEST relative error in P, (P_model - P)/P, over the kept points minimised from it (Vitor's practice, C280); both answers kept. OUTLIERS: after the least-squares stage a point with a relative P error above 15 % (three times the acceptance) is DISCARDED BY NAME (its study DOI, T and P), listed in the result and the record, and the fit repeated without it, once ('outliers { maxRelativeError 15 percent; }'). ACCEPTANCE, GRADED, the DEFAULT of C285: the maximum relative P error over all kept points is graded clean up to 5 %, warning up to 10 %, severe up to 20 % and refused above; where the normal-boiling-point condition below applies, the absolute gap is graded clean up to 1 K, warning up to 2 K, severe up to 4 K and refused above. The fit's grade is the WORSE of the two. A clean, warning or severe fit is ACCEPTED and promoted (autoPromoted, humanReviewed false) with 'fitGrade <grade>;' and the deciding numbers in its provenance entry, which the component loader voices on every run that uses it (a warning or a severe grade); a refused one is not promoted. This case declares no 'system/curationDict', so the default applies; a case that needs another acceptance declares it there, with its reason. The AmbroseWalton curve's errors on the same points are reported beside the fit's, as information.

NORMAL BOILING POINT: the record's Tb 362.9 K is judged against the range of the KEPT points (all studies span 273.04-352.77 K before any outlier is discarded): if Tb lies OUTSIDE that range, the fitted Antoine's own normal boiling point (P = 101.325 kPa) is GRADED by its absolute gap to it (the temperature limits of the acceptance below); inside it, the gap is reported and is not a condition.

EARLIER FITS, SUPERSEDED BY THIS DECLARATION @@EARLIER-BEGIN@@ C283, every usable study fitted and none held out, accepted only at max relative error <= 5 % and Tnb within 1 K (superseded by the graded acceptance of C285): WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). Objective twoStage. Antoine log10(Psat/bar) = 4.187638 - 1340.7812/(T + -41.8128), in-sample R2 0.999996 over 5 kept points, 273.04-352.77 K (10.1021/je800603z 5/5 kept). Relative error in P over the kept points: mean 0.2398 %, max 0.2609 %; AmbroseWalton on the same points: mean 1.0386 %, max 1.6667 %. Outliers discarded: none. Its own normal boiling point (101.325 kPa): 362.43 K. curate457_nrtl_methylal_dimethylCarbonate

tutorials/props/curation/curate457_nrtl_methylal_dimethylCarbonate

What it does: NRTL methylal-dimethylCarbonate regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair methylal dimethylCarbonate (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methylal (CAS 109-87-5, InChIKey NKDDWNXOKDWJAK-UHFFFAOYSA-N) + dimethylCarbonate (CAS 616-38-6, InChIKey IEJIGPNLZYLLBP-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2015.03.049 block 10 14 pts 101.33 kPa 315.89-358.96 K U 0.25-1.01 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 14 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -248.1 K, b_ji = 426.1 K over 14 kept points of 1 laboratories (0 discarded): max |dT| 1.486 K, mean 0.612 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (-248.1, 426.1). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/dimethylCarbonate-methylal.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.486 K over the 14 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2015.03.049); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate462_nrtl_nNonane_nHeptane

tutorials/props/curation/curate462_nrtl_nNonane_nHeptane

What it does: NRTL nNonane-nHeptane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair nNonane nHeptane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. nNonane (CAS 111-84-2, InChIKey BKIMMITUMNQMOS-UHFFFAOYSA-N) + nHeptane (CAS 142-82-5, InChIKey IMNFDUFMRHMDMM-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

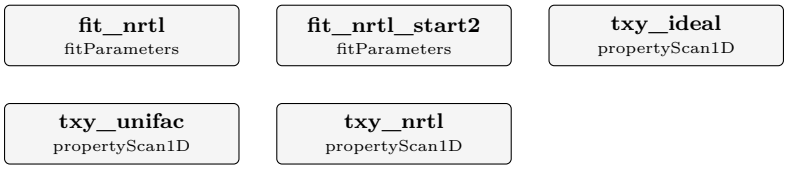
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2013.05.016 block 21 14 pts 101.3 kPa 373.30-420.70 K U 0.3-0.9 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 14 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -455.5 K, b_ji = 741.8 K over 14 kept points of 1 laboratories (0 discarded): max |dT| 0.590 K, mean 0.304 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (-455.5, 741.8). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/nHeptane-nNonane.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.590 K over the 14 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2013.05.016); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate467_nrtl_1Hexanol_aniline

tutorials/props/curation/curate467_nrtl_1Hexanol_aniline

What it does: NRTL 1Hexanol-aniline regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 1Hexanol aniline (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 1Hexanol (CAS 111-27-3, InChIKey ZSIAUFGUXNUGDI-UHFFFAOYSA-N) + aniline (CAS 62-53-3, InChIKey PAYRUJLWNCNPSJ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2010.08.010 block 14 13 pts 95.6 kPa 429.35-451.95 K U 0.45-0.45 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 13 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 866.3 K, b_ji = -497.4 K over 13 kept points of 1 laboratories (0 discarded): max |dT| 0.233 K, mean 0.134 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (866.3, -497.4). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Hexanol-aniline.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.233 K over the 13 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2010.08.010); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate492_nrtl_2Methyl1Butanol_nNDimethylformamide

tutorials/props/curation/curate492_nrtl_2Methyl1Butanol_nNDimethylformamide

What it does: NRTL 2Methyl1Butanol-nNDimethylformamide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 2Methyl1Butanol nNDimethylformamide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 2Methyl1Butanol (CAS 137-32-6, InChIKey QPRQEDXDYOZYLA-UHFFFAOYSA-N) + nNDimethylformamide (CAS 68-12-2, InChIKey ZMXDDKWLCZADIW-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je3012925 block 9 14 pts 101.3 kPa 402.61-421.90 K U 0.12-0.24 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 14 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 660.8 K, b_ji = -422.0 K over 14 kept points of 1 laboratories (0 discarded): max |dT| 0.366 K, mean 0.192 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (660.8, -422.0). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/2Methyl1Butanol-nNDimethylformamide.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.366 K over the 14 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je3012925); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate498_nrtl_2Methyl2Propanol_nitrobenzene

tutorials/props/curation/curate498_nrtl_2Methyl2Propanol_nitrobenzene

What it does: NRTL 2Methyl2Propanol-nitrobenzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 2Methyl2Propanol nitrobenzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 2Methyl2Propanol (CAS 75-65-0, InChIKey DKGAVHZHDRPRBM-UHFFFAOYSA-N) + nitrobenzene (CAS 98-95-3, InChIKey LQNUZADURLCDLV-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2005.08.011 block 34 12 pts 94.95 kPa 355.75-437.05 K U 1.02-1.02 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 12 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 647.0 K, b_ji = -693.3 K over 12 kept points of 1 laboratories (0 discarded): max |dT| 1.685 K, mean 1.186 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (647.0, -693.3). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/2Methyl2Propanol-nitrobenzene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.685 K over the 12 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.jct.2005.08.011); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate524_nrtl_nHexane_oXylene

tutorials/props/curation/curate524_nrtl_nHexane_oXylene

What it does: NRTL nHexane-oXylene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair nHexane oXylene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. nHexane (CAS 110-54-3, InChIKey VLKZOEOYAKHREP-UHFFFAOYSA-N) + oXylene (CAS 95-47-6, InChIKey CTQNGGLPUBDAKN-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/-solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je3002283 block 8 12 pts 101.3 kPa 344.40-414.60 K U 0.1-0.1 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 12 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 337.0 K, b_ji = -213.9 K over 12 kept points of 1 laboratories (0 discarded): max |dT| 1.141 K, mean 0.595 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (337.0, -213.9). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/nHexane-oXylene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.141 K over the 12 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je3002283); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate529_nrtl_pCresol_nitrobenzene

tutorials/props/curation/curate529_nrtl_pCresol_nitrobenzene

What it does: NRTL pCresol-nitrobenzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair pCresol nitrobenzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. pCresol (CAS 106-44-5, InChIKey IWDCLRJOBJJRNH-UHFFFAOYSA-N) + nitrobenzene (CAS 98-95-3, InChIKey LQNUZADURLCDLV-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2006.12.010 block 22 12 pts 94.95 kPa 473.55-480.55 K U 1.37-1.37 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 12 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 30.9 K, b_ji = -18.2 K over 12 kept points of 1 laboratories (0 discarded): max |dT| 0.524 K, mean 0.251 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on A DIFFERENT pair (38.7, -25.8). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/nitrobenzene-pCresol.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.524 K over the 12 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2006.12.010); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate534_nrtl_1Pentanol_nHexane

tutorials/props/curation/curate534_nrtl_1Pentanol_nHexane

What it does: NRTL 1Pentanol-nHexane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 1Pentanol nHexane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 1Pentanol (CAS 71-41-0, InChIKey AMQJEAYHLZJPGS-UHFFFAOYSA-N) + nHexane (CAS 110-54-3, InChIKey VLKZOEOYAKHREP-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

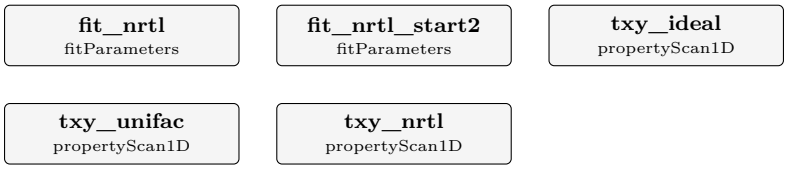
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je700285j block 2 13 pts 101.3 kPa 341.90-342.90 K U 0.3-0.3 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 13 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -339.9 K, b_ji = 1224.4 K over 13 kept points of 1 laboratories (0 discarded): max |dT| 0.188 K, mean 0.127 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on A DIFFERENT pair (3000.0, 641.0). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/1Pentanol-nHexane.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.188 K over the 13 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je700285j); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

WRITTEN BY bin/choupo-curate pair methanol ethyleneCarbonate (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methanol (CAS 67-56-1, InChIKey OKKJLVBELUTLKV-UHFFFAOYSA-N) + ethyleneCarbonate (CAS 96-49-1, InChIKey KMTRUDSVKNLOMY-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je049859c block 2 13 pts 101.3 kPa 339.56-414.75 K U 0.99-0.99 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 13 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 671.8 K, b_ji = -110.5 K over 13 kept points of 1 laboratories (0 discarded): max |dT| 1.337 K, mean 0.861 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (671.8, -110.5). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/ethyleneCarbonate-methanol.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.337 K over the 13 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je049859c); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate563_nrtl_tetrahydrofuran_nButanol

tutorials/props/curation/curate563_nrtl_tetrahydrofuran_nButanol

What it does: NRTL tetrahydrofuran-nButanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair tetrahydrofuran nButanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. tetrahydrofuran (CAS 109-99-9, InChIKey WYURNTSHIVDZCO-UHFFFAOYSA-N) + nButanol (CAS 71-36-3, InChIKey LRHPLDYGYMQRHN-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

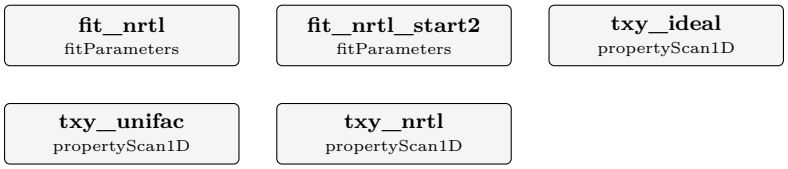
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je030141r block 50 11 pts 95.8 kPa 337.25-370.65 K U 1.31-1.31 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 11 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 1110.3 K, b_ji = -301.0 K over 11 kept points of 1 laboratories (0 discarded): max |dT| 0.900 K, mean 0.581 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (1110.3, -301.0). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/nButanol-tetrahydrofuran.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.900 K over the 11 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je030141r); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate568_nrtl_2Butanol_pCresol

tutorials/props/curation/curate568_nrtl_2Butanol_pCresol

What it does: NRTL 2Butanol-pCresol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 2Butanol pCresol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 2Butanol (CAS 78-92-2, InChIKey BTANRVKWQNVYAZ-UHFFFAOYSA-N) + pCresol (CAS 106-44-5, InChIKey IWDCLRJOBJJRNH-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2006.03.018 block 41 10 pts 95.23 kPa 374.15-452.25 K U 1.02-1.02 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 10 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 406.0 K, b_ji = -384.8 K over 10 kept points of 1 laboratories (0 discarded): max |dT| 0.883 K, mean 0.469 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (406.0, -384.8). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/2Butanol-pCresol.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.883 K over the 10 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2006.03.018); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate573_nrtl_methylal_benzene

tutorials/props/curation/curate573_nrtl_methylal_benzene

What it does: NRTL methylal-benzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair methylal benzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. methylal (CAS 109-87-5, InChIKey NKDDWNXOKDWJAK-UHFFFAOYSA-N) + benzene (CAS 71-43-2, InChIKey UHOVQNZJYSORNB-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je049681u block 13 10 pts 95.96 kPa 315.25-339.75 K U 0.51-0.51 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 10 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

curate592_nrtl_tetrahydrofuran_2Butanol

tutorials/props/curation/curate592_nrtl_tetrahydrofuran_2Butanol

What it does: NRTL tetrahydrofuran-2Butanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair tetrahydrofuran 2Butanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. tetrahydrofuran (CAS 109-99-9, InChIKey WYURNTSHIVDZCO-UHFFFAOYSA-N) + 2Butanol (CAS 78-92-2, InChIKey BTANRVKWQNVYAZ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je030141r block 52 9 pts 95.8 kPa 340.35-366.45 K U 1.31-1.31 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 9 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 123.5 K, b_ji = -120.1 K over 9 kept points of 1 laboratories (0 discarded): max |dT| 0.214 K, mean 0.130 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (123.6, -120.2). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/2Butanol-tetrahydrofuran.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.214 K over the 9 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je030141r); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate597_nrtl_acetonitrile_nButanol

tutorials/props/curation/curate597_nrtl_acetonitrile_nButanol

What it does: NRTL acetonitrile-nButanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair acetonitrile nButanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. acetonitrile (CAS 75-05-8, InChIKey WEVYAHXRMPXWCK-UHFFFAOYSA-N) + nButanol (CAS 71-36-3, InChIKey LRHPLDYGYMQRHN-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2006.07.014 block 15 9 pts 94.83 kPa 353.85-380.65 K U 1.38-1.39 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 9 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 698.5 K, b_ji = -441.7 K over 9 kept points of 1 laboratories (0 discarded): max |dT| 0.343 K, mean 0.234 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (698.5, -441.7). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/acetonitrile-nButanol.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.343 K over the 9 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.jct.2006.07.014); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate602_nrtl_dimethylCarbonate_ethyleneCarbonate

tutorials/props/curation/curate602_nrtl_dimethylCarbonate_ethyleneCarbonate

What it does: NRTL dimethylCarbonate-ethyleneCarbonate regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair dimethylCarbonate ethyleneCarbonate (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. dimethylCarbonate (CAS 616-38-6, InChIKey IEJIGPNLZYLLBP-UHFFFAOYSA-N) + ethyleneCarbonate (CAS 96-49-1, InChIKey KMTRUDSVKNLOMY-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je049859c block 0 11 pts 101.3 kPa 363.96-482.07 K U 0.99-0.99 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 11 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 664.9 K, b_ji = -163.7 K over 11 kept points of 1 laboratories (0 discarded): max |dT| 1.139 K, mean 0.682 K, graded warning (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (664.9, -163.7). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/dimethylCarbonate-ethyleneCarbonate.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade warning – max |dT| 1.139 K over the 11 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je049859c); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate607_nrtl_acetonitrile_2Butanol

tutorials/props/curation/curate607_nrtl_acetonitrile_2Butanol

What it does: NRTL acetonitrile-2Butanol regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair acetonitrile 2Butanol (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. acetonitrile (CAS 75-05-8, InChIKey WEVYAHXRMPXWCK-UHFFFAOYSA-N) + 2Butanol (CAS 78-92-2, InChIKey BTANRVKWQNVYAZ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2006.07.014 block 17 8 pts 94.83 kPa 352.85-359.95 K U 1.38-1.39 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

curate621_nrtl_nitrobenzene_dimethylSulfoxide

tutorials/props/curation/curate621_nrtl_nitrobenzene_dimethylSulfoxide

What it does: NRTL nitrobenzene-dimethylSulfoxide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair nitrobenzene dimethylSulfoxide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. nitrobenzene (CAS 98-95-3, InChIKey LQNUZADURLCDLV-UHFFFAOYSA-N) + dimethylSulfoxide (CAS 67-68-5, InChIKey IAZDPXIOMUYVGZ-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role non-volatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.fluid.2007.08.001 block 16 8 pts 95.3 kPa 458.15-479.05 K U 0.7-0.7 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 8 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -568.0 K, b_ji = 1692.7 K over 8 kept points of 1 laboratories (0 discarded): max |dT| 0.466 K, mean 0.363 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (-568.0, 1692.7). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/dimethylSulfoxide-nitrobenzene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.466 K over the 8 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.fluid.2007.08.001); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate626_nrtl_trichloroethylene_nHeptane

tutorials/props/curation/curate626_nrtl_trichloroethylene_nHeptane

What it does: NRTL trichloroethylene-nHeptane regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair trichloroethylene nHeptane (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. trichloroethylene (CAS 79-01-6, InChIKey XSTXAVWGXDQKEL-UHFFFAOYSA-N) + nHeptane (CAS 142-82-5, InChIKey IMNFDUFMRHMDMM-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

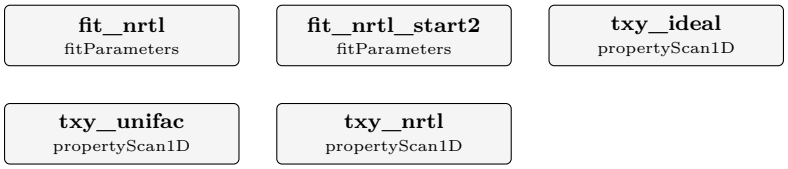
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je0301085 block 27 8 pts 95.8 kPa 358.85-365.45 K U 0.25-1 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 8 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -239.3 K, b_ji = 425.9 K over 8 kept points of 1 laboratories (0 discarded): max |dT| 0.638 K, mean 0.223 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (-239.3, 425.9). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/nHeptane-trichloroethylene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.638 K over the 8 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je0301085); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate631_nrtl_Dichloroethane_nitrobenzene

tutorials/props/curation/curate631_nrtl_Dichloroethane_nitrobenzene

What it does: NRTL Dichloroethane-nitrobenzene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair Dichloroethane nitrobenzene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. Dichloroethane (CAS 107-06-2, InChIKey WSLDOOZREJYCGB-UHFFFAOYSA-N) + nitrobenzene (CAS 98-95-3, InChIKey LQNUZADURLCDLV-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1021/je0301085 block 29 7 pts 94.6 kPa 358.85-417.25 K U 0.26-0.26 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 7 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 272.1 K, b_ji = -273.3 K over 7 kept points of 1 laboratories (0 discarded): max |dT| 0.305 K, mean 0.178 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (272.1, -273.3). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/Dichloroethane-nitrobenzene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.305 K over the 7 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1021/je0301085); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate645_nrtl_224Trimethylpentane_pXylene

tutorials/props/curation/curate645_nrtl_224Trimethylpentane_pXylene

What it does: NRTL 224Trimethylpentane-pXylene regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair 224Trimethylpentane pXylene (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. 224Trimethylpentane (CAS 540-84-1, InChIKey NHTMVDHEPJAVLT-UHFFFAOYSA-N) + pXylene (CAS 106-42-3, InChIKey URLKBWYHVLBVBO-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2005.04.006 block 22 6 pts 95.8 kPa 372.75-401.65 K U 1.01-1.01 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 6 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = -310.2 K, b_ji = 475.4 K over 6 kept points of 1 laboratories (0 discarded): max |dT| 0.082 K, mean 0.058 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (-310.2, 475.4). PROMOTED on 2026-11-10 into data/standards/parameters/NRTL/224Trimethylpentane-pXylene.dat as reviewStatus autoPromoted, humanReviewed false, because: fit grade clean – max |dT| 0.082 K over the 6 kept points (limits 1 / 2 / 4 K), one liquid across the validity span – it rests on ONE laboratory's measurements (doi 10.1016/j.jct.2005.04.006); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@

WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

curate650_nrtl_ethylBenzene_nNDimethylacetamide

tutorials/props/curation/curate650_nrtl_ethylBenzene_nNDimethylacetamide

What it does: NRTL ethylBenzene-nNDimethylacetamide regressed by the curation pipeline to every laboratory's measured bubble temperatures (ThermoML locates, the articles source), graded by max |dT| (clean 1 K, warning 2 K, severe 4 K, refused above; C285, C286)

The story: AN NRTL PAIR FROM EVERY LABORATORY'S MEASUREMENTS.

WRITTEN BY bin/choupo-curate pair ethylBenzene nNDimethylacetamide (DEV.md 4c C284, the bulk run; record docs/design/binary-pairs-from-open-measurements.md section 11).

THE DECLARATION – WRITTEN AND COMMITTED BEFORE ANY FIT RAN (several declarations of the bulk run share one commit).

IDENTITY. ethylBenzene (CAS 100-41-4, InChIKey YNQLUTRBYVCPMQ-UHFFFAOYSA-N) + nNDimethylacetamide (CAS 127-19-5, InChIKey FXHOOIRPVKKKFG-UHFFFAOYSA-N), joined to the archive through identity.json – never by name. CLASS (C284): both records are volatile molecular liquids (no role nonvolatile/solute, no dissociatesTo, no charge, no solid, a vapour-pressure model), and every measured temperature lies below both critical temperatures.

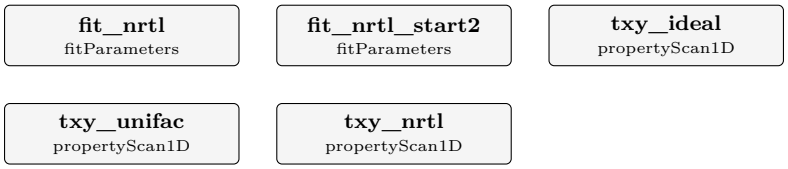
NO MEASURED SERIES IN THIS TREE. constant/archiveDatasets names each dataset (DOI, NIST URL, article sha256, extraction selector, extract sha256); 'bin/choupo-curate fetch' writes the points into constant/archiveExtracts/, which is gitignored.

STUDIES: every bubble-temperature block of the pair at or below 110 kPa with a declared uncertainty (1 block(s)). FITTED, ALL OF THEM (1): 10.1016/j.jct.2004.11.015 block 28 6 pts 94.7 kPa 399.75-406.35 K U 7.08-7.08 K SET ASIDE BY THE EXTRACTION RULES, BY NAME: (none)

THE RULE (DEV.md 4c C283 amended, C284). Every laboratory above is fitted; none is held out (the C16 partition and its band are retired as the acceptance test). NRTL, a_ij = a_ji = 0, alpha = 0.30 fixed: two parameters (b_ij, b_ji); each point weighted by 1/U, U its own stated expanded uncertainty. Objective twoStage (least squares, then minimax; T_bubble absolute, in K). OUTLIERS: after a least-squares stage over every point, a point with |T_model - T| > 3 K is discarded BY NAME ('discard' on its evidence entry, listed below) and the fit repeated without it. THE GRADED ACCEPTANCE (DEV.md 4c C285, applied to pairs by C286): max |T_model - T| over the KEPT points is GRADED – clean up to 1 K, warning up to 2 K, severe up to 4 K, refused above; a point with no bubble point refuses. C283's relative clause (5 / 10 / 20 %) judges composition; this fit has no composition residual, so only the temperature clause applies. Every grade but refused is accepted and promoted (autoPromoted, humanReviewed false) with 'fitGrade' and its max |dT| in the record's provenance; the engine voices a warning or a severe grade on every run that reads the pair. A pair that splits ONE liquid inside its validity span is not promoted, whatever its grade (arm f). Two starts: (0, 0) and (800, -400).

OUTLIERS DISCARDED AFTER THE LEAST-SQUARES STAGE: @@OUTLIERS-BEGIN@@ none: every one of the 6 points lies within 3 K after the least-squares stage. @@OUTLIERS-END@@

@@RESULT-BEGIN@@ WHAT THE RUN FOUND (pinned in 'expected'; measured, not argued). fit_nrtl: b_ij = 676.3 K, b_ji = 355.9 K over 6 kept points of 1 laboratories (0 discarded): max |dT| 0.691 K, mean 0.452 K, graded clean (limits 1 / 2 / 4 K) → accepted. fit_nrtl_start2 lands on the same pair (676.3, 355.9). NOT PROMOTABLE (fit grade clean, max |dT| 0.691 K): the pair splits ONE liquid inside its own validity span (check_regressed_pairs arm f) – predicts a LIQUID-LIQUID SPLIT at 399.75 K (x_ethylBenzene 0.534 .. 0.649), inside its own validity span 399.75-406.35 K – its evidence is bubble temperatures of ONE liquid, which a bubble scan cannot contradict; a pair that splits that liquid stays in its case, not the catalogue (or it DECLARES 'liquidLiquid true;' with tie-line evidence and a gap band) – it rests on ONE laboratory's measurements (doi 10.1016/j.jct.2004.11.015); nothing here tells its systematic error from the model's (DEV.md 4c C290) @@RESULT-END@@



WHAT IS NOT CLAIMED. The pair is correct at these pressures and in this frame (ideal-gas vapour, the catalogue's own vapour-pressure records); the measurements were transcribed by the archive and have NOT been read back against the articles (the CHECKLIST that 'fetch' writes is the aid).

electrolyte

The theory you need. Ions interact at long range (Debye–Hückel, $\sqrt{I}$ law) and short range (ion–ion, ion–solvent). Choupo's ladder: Davies (charge-only, $I \leq 0.5$), single-salt Pitzer ($\beta_0, \beta_1, C^{\varphi}$; to $I \sim 6$, and with the Silvester–Pitzer T-functions to 300°C), multi-ion Pitzer–HMW (per-ion, mixing terms θ, ψ – seawater-class brines), and eNRTL (local-composition; single-salt, mixed-solvent, and the 2009 symmetric multi-salt with both published and Gibbs–Duhem-consistent formulations). Speciation solves mass action + charge balance by Newton in log-molality space; saturation indices SI = $\log(\mathrm{IAP}/K_{\mathrm{sp}})$ flag scaling. Expect: models to DISAGREE above their validity (γ divergence is the lesson, e.g. Davies vs Pitzer at RO recoveries), and every activity model to announce itself. *Full derivation: Theory Guide, the electrolyte + speciation chapters.*

archer01_nacl_cold_to_hot

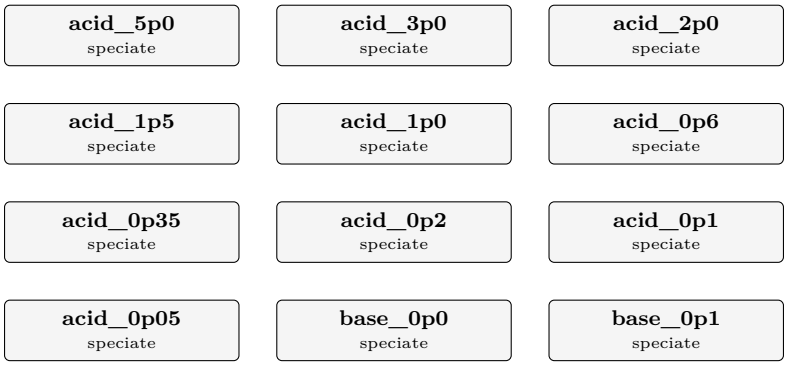
tutorials/props/electrolyte/archer01_nacl_cold_to_hot

What it does: NaCl Pitzer 0-100 C vs Archer 1992 – the cold edge the freezing curve stands on

The story: The catalogue's NaCl Pitzer surface (Appelo 25 C parameters + SP77 T-functions) against Archer, J. Phys. Chem. Ref. Data 21 (1992) 793, DOI 10.1063/1.555915, Tables 9 (phi) and 10 (gamma_pm) – HIS fitted equation's check values ("presented only as a means to test the validity of coding", the paper's own words), at 273, 298, 323 and 373 K.

WHY THE 273 K ROW IS THE POINT: the SP77 temperature extension was fitted ABOVE 25 C, and the freezing-point curve (fpd01_nacl_freezing) leans on that surface BELOW 0 C as an announced extrapolation. This case measures what the extrapolation costs at the last anchor before the ice field – the op announces the T-window violation at 273 K, and the AAD against Archer says whether the announced risk is a real one at the cold edge.

WHAT THIS COMPARISON IS, said precisely: Archer's tables are values of an independent CRITICAL FIT (his global equation, 250-600 K), not raw measurements, and his database overlaps the corpora SP77 drew on. Agreement here is CROSS-EVALUATION CONSISTENCY between two independent fits of overlapping data – stronger than fit-consistency (our parameters never saw Archer's equation), weaker than agreement with an independent measurement. The Hamer & Wu case (pitzer_gamma_hamer_wu) plays the same role at 25 C; this case extends it across T.



Temperatures are the table's printed values (273 K, not 273.15). If Archer meant T+0.15 K the shift in gamma_pm is below 2e-4 – inside the quoted AADs either way, and stated here so the reading is a recorded choice, not an accident.

bjerrum01_carbonate_pH

tutorials/props/electrolyte/bjerrum01_carbonate_pH

What it does: Carbonate speciation across the pH range – the Bjerrum plot, titrated

The story: THE SPECIATION OF A CARBONATE SOLUTION ACROSS THE WHOLE pH RANGE – the diagram every textbook draws, built the way Choupo has to build it.

THE ONE THING THAT MAKES THIS DIFFERENT FROM THE TEXTBOOK VERSION: here the pH is NOT an axis you set – and that is a CHOICE this case makes, in one word, which you can read three screens down. A textbook draws the fractions against pH by substituting pH into the mass-action expressions, which is arithmetic and always works. Choupo can do that too: 'pH 7.8;' is a legal declaration, it fixes [H+], and it DROPS the electroneutrality row – the run then reports the net charge the composition carries ('pH GIVEN – this is the net charge the analysis carries') instead of forcing it to zero. That mode exists because a laboratory sheet reports a MEASURED pH, which is a datum. It is not what this case wants. Every op below declares 'pH solve;' instead, so [H+] joins the unknowns and the charge balance is the equation that closes the system. The price of that choice is the whole lesson: each point had to be a beaker somebody could weigh out, the 44 of them differ only in what is IN the beaker, and the x-axis is a RESULT, exactly as it is in a laboratory.

WHAT IS ACTUALLY IN EACH BEAKER. Total carbonate is held at 1 mmol/kg throughout. The 44 points differ only in how much strong acid or strong base sits beside it, and each one is a real neutral mixture somebody could weigh out:

Cl / C_T = 5 ... 0.05 hydrochloric acid added to dissolved CO2 Na / C_T = 0 dissolved CO2 alone (H2CO3) Na / C_T = 1 sodium bicarbonate (NaHCO3) Na / C_T = 2 sodium carbonate (Na2CO3) Na / C_T = 2 ... 8 sodium carbonate + caustic soda

That is what 'totalsBasis stoichiometric;' declares below: these totals are neutral-molecule feeds, so the water-analysis charge-imbalance check – which is right for a LAB SHEET, where an imbalance means somebody mismeasured – does not apply. Here the imbalance IS the titrant, and the electroneutrality equation IS the weak-acid pH. Declaring it changes no number: it changes what the engine says about them.

WHAT TO LOOK FOR, in the order a student should look:

1. THE TWO CROSSOVERS LAND ON THE TWO pK's, AND NOBODY PUT THEM THERE. CO2(aq) and HCO3- are equal at pH 6.341; the record's log K1 is 6.352. HCO3- and CO3– are equal at pH 10.262; log K2 is 10.329. Both crossover pH's are INTERPOLATED between the two beakers that bracket them – the axis is 44 sampled points, not a continuum, and no beaker lands exactly on a crossing. Neither pK was used as an input to any point – they are the mass- action constants inside the network, and the crossover is where the titration happens to arrive. The small shift DOWN in both is the activity coefficients, while a textbook plot takes every gamma as 1. The first is moved by gamma_HCO3 alone (about 0.975 there; CO2(aq) is neutral) – gamma_CO3 is 0.90 at that crossover but carbonate is a trace there and moves nothing. The second is moved by the ratio gamma_CO3 / gamma_HCO3, 0.81 against 0.95.

2. THE THREE FRACTIONS DO NOT SUM TO ONE. They dip to 0.99966 through the middle of the range, and the missing carbon is NOT round-off: it is 'NaHCO3aq', the sodium-bicarbonate ION PAIR, which the curated chemistry carries and the three-curve drawing has no place for. The titrant is not a

spectator. Look at the ‘m_NaHCO3aq‘ diagnostic – and note where it is ABSENT: the two beakers with no sodium in them (the acid side, and Na/C_T = 0) have no such species to report, and the engine REFUSES to report a species that is not in the table rather than printing a zero. Absent and zero are different claims.

3. THE ACTIVITY COEFFICIENT OF THE DIVALENT ION MAKES A U. gamma_CO3 runs 0.74 at the acid end, up to 0.98 near Na/C_T = 0 where the ionic strength is lowest, and back down to 0.67 at the alkaline end – because BOTH ends of a titration are loaded with strong electrolyte and only the middle is dilute. A textbook diagram takes every gamma as 1 at every pH, which is the one assumption that is worst exactly where the diagram is usually read.

4. THE SATURATION INDICES ARE THERE ALL ALONG. Every point reports SI_nahcolite / SI_natron / SI_trona – how far the solution is from precipitating a sodium carbonate mineral. At 1 mmol/kg they stay far below zero, which is why this stays a clean acid-base diagram; make C_T a hundred times larger and the diagram acquires a ceiling.

THE CONSTANTS, and their lineage: log K1 = 6.352, log K2 = 10.329 and Kw = 1e-14 at 25 C, from the USGS PHREEQC database (public domain), which is where data/standards/chemistry/{CO2aq,CO3}-formation.dat and water-dissociation.dat come from. Each carries the van’t Hoff dH and the full analytic log K(T), so this whole diagram can be redrawn at another temperature and both pK’s will move – change ‘temperature‘ below and watch which crossover moves further.

NOT VALIDATED AGAINST MEASUREMENT. This case is a STRUCTURAL witness: it shows that the engine’s speciation network, its activity model and its charge balance compose into the diagram the chemistry predicts. No titration data is compared against; the two crossovers landing near the two pK’s is an internal consistency check on the assembly, not agreement with an experiment.

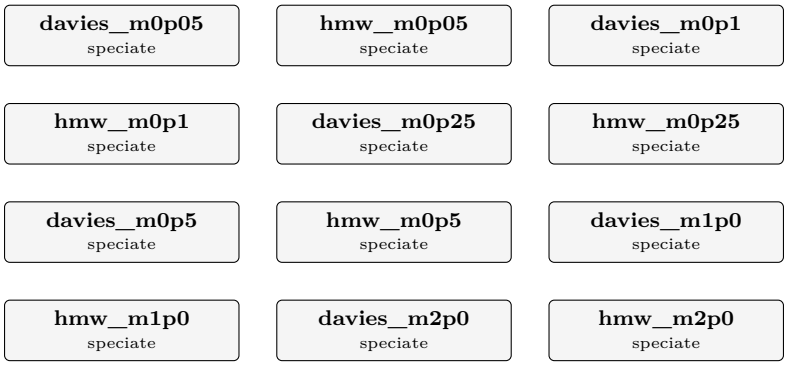
composition01_nacl

tutorials/props/electrolyte/composition01_nacl

What it does: Apparent-salt input: the analysis is given as composition { NaCl 2.0 mol/kg }, expanded to Na + Cl ion totals through NaCl's dissociatesTo, with electroneutrality validated (Sum nu∗charge = 0). Byte-identical to writing totals { Na 2.0; Cl 2.0 } by hand.

The speciate op expands each salt to ion totals through its dissociatesTo (NaCl → Na 1, Cl 1), and validates electroneutrality (Sum nu∗charge = 0) so a formulated-salts input can never silently unbalance charge. This is byte-identical to writing the ions by hand (totals { Na 2.0; Cl 2.0 }): SI_halite -0.953, feed charge imbalance 0.00%.



composition{} is the apparent-salt input mode; analyticalTotals{} / totals{} stay as the mode for waters measured directly in ions/masters (roadmap Phase B).

davies01_band_edge

tutorials/props/electrolyte/davies01_band_edge

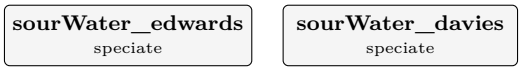
What it does: The Davies band edge, MEASURED: gamma_pm and a_w for NaCl under Davies beside PitzerHMW on identical brines, m = 0.05..6 mol/kg – the cross-model curve behind every 'indicative beyond I ~ 0.5' advisory

The story: THE DAVIES BAND EDGE, measured instead of remembered.

Same NaCl brine, same totals, same solved pH – speciated twice per rung: once under Davies (charge-only, the teaching rung; phi = 1 water activity) and once under PitzerHMW (per-ion virials; rigorous phi). What this measures is CROSS-MODEL divergence between two of Choupo's own engines – weaker than agreement with an independent measurement, and said so; the Pitzer surface itself is anchored elsewhere (pitzer01_nacl, archer01_nacl_cold_to_hot, pitzer_gamma_hamer_wu).

WHY IT EXISTS: every electrolyte run above I ~ 0.5 mol/kg carries the advisory "Davies ... INDICATIVE"; the marcilla01/02 anchor contacts put numbers on what that costs at saturation (halite at 3.65 vs the measured 6.14 mol/kg). This case turns the advisory into a CURVE – per rung, gamma_Na, gamma_Cl and a_w under both closures, side by side. No threshold is invented: the divergence grows smoothly and there is no principled cut, so the table reports and the reader judges (the same posture as the neglected-dCp advisory in SolidPhase).

Same NaCl brine speciated twice per rung: Davies (teaching rung, charge-only, $\varphi = 1$) beside PitzerHMW (per-ion virials), 298.15 K. Cross-model divergence between two in-tree engines — weaker than an independent measurement and said so; the Pitzer surface itself is anchored elsewhere (pitzer01_nacl, archer01_nacl_cold_to_hot, pitzer_gamma_hamer_wu).



∗ The "I ~ 0.5 trust band" every advisory quotes is real: the $\gamma\pm$ error crosses ~2–8 % over m = 0.25–0.5 and explodes beyond it (Davies' +0.3·I term has no physics above the band — it is the fit's tail). ∗ At m = 6, Davies reports SI_halite = +1.10 where PitzerHMW reports -0.022 — the rigorous rung sits essentially AT saturation beside Archer's peritectic (6.096 mol/kg), and its a_w = 0.7592 beside the literature ≈ 0.753. This is the whole quantitative story of the marcilla01/02 anchor gaps (Davies saturating at 3.65 vs 6.14 mol/kg; the too-wet organic from a_w ≈ 0.88): the model, not the machinery.

edwards01_sour_water_activity

tutorials/props/electrolyte/edwards01_sour_water_activity

What it does: Edwards et al. (1978) activity model on a sour-water NH3/CO2 brine – the molecular solutes get a real gamma from the model their parameters were regressed in, where Davies can only return 1.

The story: the WITNESS for the ‘edwardsPitzer‘ activity model.

WHAT THIS CASE IS FOR. Choupo already carries two aqueous activity models, and each fails this fluid in its own way:

‘davies‘ is a charge-only correlation. Every singly-charged ion gets the same gamma and every NEUTRAL solute gets gamma = 1 – exactly, by construction, at every ionic strength. A sour-water stripper’s whole difficulty is the volatility of dissolved NH3 and CO2, i.e. of two NEUTRAL molecules, and Davies cannot say anything about either. ‘pitzerHMW‘ is the Harvie-Moller-Weare parameterisation: a DIFFERENT truncation, with a different parameter set (beta2, C-phi, theta, psi), fitted to strong electrolytes. Its numbers are not Edwards’ numbers, and Edwards’ numbers are not valid inside its equation.

‘edwardsPitzer‘ is the truncation Edwards, Maurer, Newman & Prausnitz (AIChE J. 24(6):966-976, 1978) REGRESSED HIS NH3/CO2/H2S/SO2 PARAMETERS IN: Pitzer’s expansion cut after the second virial coefficient, extended to molecular solutes. Using his parameters anywhere else would be quoting his numbers under someone else’s equation.

THE COMPOSITION is the sour-water region his Table 7 anchors: ammonia in large excess over carbon dioxide, the carbonate and carbamate networks both live, at an ionic strength around 1 mol/kg where a dilute correlation has no business being trusted.

WHAT TO READ IN THE OUTPUT. Run the two operations side by side and compare ‘gamma_NH3aq‘ and ‘gamma_CO2aq‘:

under ‘davies‘ they are 1.000000 and 1.000000. Not approximately – exactly, because the model’s gamma is a function of charge alone and the charge is zero. A student who has only ever seen Davies may not realise this is a STRUCTURAL silence rather than a small correction. under ‘edwardsPitzer‘ they are 1.0224 and 1.0101: both SALTED OUT, NH3 rather more than CO2. Both rise because both Table 4 self-terms are positive at 25 C – Eq 14 gives beta0(NH3,NH3) = 0.01522 and beta0(CO2,CO2) = 0.00822 kg/mol – and NH3 rises further because it is the more abundant of the two by three orders of magnitude, so its own self-term dominates its Eq 8 sum.

THE SPECIATION MOVES TOO, and by far more than the gammas: the answer is I = 2.78 against Davies’ 1.78, with m_NH3aq 0.41 against 1.01. That is not a molecular effect at all – it is the IONIC one. Davies at I ~ 2 returns gamma_NH4 = 0.956, because its bracket saturates and then turns back up; Edwards’ Eq 8 returns 0.301 at the same charge. The NH4+/NH3aq equilibrium reads those gammas, so the split follows. The lesson is the one the advisory prints on the Davies run: a dilute correlation used far outside its band does not merely lose accuracy, it changes the answer’s SHAPE.

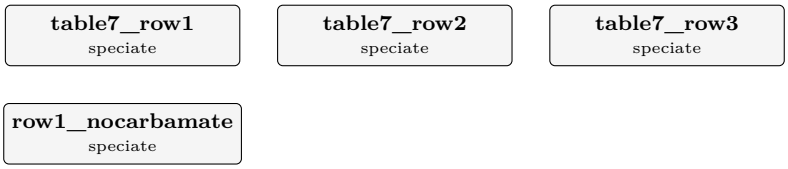
Neither number here is validated against measurement – see below.

WHAT THIS CASE IS ∗NOT∗. It is not the Table 7 anchor. Reproducing Table 7 needs the vapour side – Henry’s constants on the paper’s own convention, the two-phase equilibrium, the total pressure – and that slice is BUILT: ‘edwards02_table7_vle‘ (2026-08-23; record in docs/design/sour-water-stripper-scope.md section 6c). This case validates the ACTIVITY SURFACE alone, which is the piece the model owns.

WHAT IS AND IS NOT VALIDATED HERE. This case is a STRUCTURAL witness: it proves the model is wired, that its five parameter rules fire and are labelled, and that a neutral solute gets a gamma. It does NOT validate any number against data – there is no measurement in it. The kernel itself is separately checked against two closed forms the paper supplies (the Eq 8a low-dissociation limit and the Debye-Huckel limiting law), and the measured-vs-computed comparison is Table 7 – edwards02_table7_vle. A green run here means "the machine is right", never "the answer is right".

HONESTY ABOUT THE PARAMETERS. Edwards measured exactly one family: beta0 for LIKE molecule pairs (Eq 14, Table 4). Every other entry in the matrix Eq 8 sums over is ESTIMATED from those by his Eqs 21-24, and the paper calls both of its parameter tables "preliminary results subject to change as more and better data become available". The engine prints, at verbosity >= 3, WHICH RULE produced each number – one measured family and four estimation routes – so nothing here can be mistaken for a measured constant.

DATA SCOPE: SEALED (bin/choupo-import). The case carries its own species, reactions and EdwardsPitzer parameter records under constant/, each named and sha256-verified by constant/propertyManifest, and the runtime is FORBIDDEN the installation catalogue.



Sealing this case is where the importer's dependency closure was found not to know the EdwardsPitzer parameter home. The first seal kept 9 of the 28 pair parameters – the Bronsted like-sign zeros, which need no record at all – and the case still RAN, still converged, and answered with 19 terms missing: gamma_HCO3 and gamma_NH4 identical (the charge-only Debye-Huckel fallback) and both neutral gammas exactly 1, which is what a Davies run prints. Nothing refused. The importer now compares the staged sealed run against this case's own 'expected' golden, because running is not agreeing.

edwards02_table7_vle

tutorials/props/electrolyte/edwards02_table7_vle

What it does: Edwards (1978) Table 7 anchor: NH3-CO2-H2O VLE at 100 degC – the paper's own predictions reproduced from its own equations, the experiment quoted as context.

The story: the LITERATURE ANCHOR for the edwardsPitzer model: Table 7 of Edwards, Maurer, Newman & Prausnitz, AIChE J. 24(6):966-976 (1978) – NH3-CO2-H2O at 100 degC, three points.

edwards01 is the STRUCTURAL witness: it proves the activity surface is wired, and its own header says none of its numbers is validated against anything. This case is the validation it points at. For each Table 7 point the paper states the total molalities of ammonia and carbon dioxide in the LIQUID and predicts the speciation (molecular NH3 and CO2, ionic strength) and the VAPOUR above it (y_NH3, y_CO2, total pressure). The whole model stack here is the paper's own:

liquid activities Eq 8/10 (edwardsPitzer, the case surface) equilibria K(T) Eq 7 / Table 1 + Eq 20 (case-local chemistry/) Henry's constants Eq 13 / Table 3 (parameters/EdwardsPitzer/henry-∗) pressure correction Eq 11 / Table 2 (vInfinity in the same records) vapour side Eq 5/6 (the speciate op's vapour{} block)

WHAT IS COMPARED, AND AGAINST WHAT. Table 7 carries TWO different columns and conflating them would be dishonest:

the paper's own PREDICTIONS (column I) – a code-to-code comparison. Those are the golden values here, with ONE declared gap: the paper computes vapour-phase fugacity coefficients from a model its transcription does not carry, so this case declares 'fugacity ideal;' (phi = 1) and the residual disagreement is expected to be of the size of that correction (a few percent at 2-3 atm), plus the numerical difference between two implementations of Eqs 7-24.

the EXPERIMENT (Otsuka et al. 1960) – quoted below as CONTEXT, never as a target. The paper's OWN agreement with it is rough (first row: y_NH3 0.066 measured vs 0.123 predicted – a factor of two) and the paper says so plainly. A student reading this case sees a correlation reproduced closely and its real-world agreement stated honestly, which is the opposite of a tool that prints one number.

Table 7, the paper's column I (the golden targets here): row mNH3tot mCO2tot m_NH3 m_CO2 I y_NH3 y_CO2 P[atm] 1 2.90 1.45 1.245 0.014 1.50 0.123 0.494 2.51 2 3.71 1.14 2.279 0.0056 1.26 0.293 0.230 1.98 3 4.30 0.907 3.087 0.0030 1.01 0.407 0.116 1.97 The experiment (Otsuka 1960, context only): 1 0.066 0.506 3.15 2 0.274 0.202 2.08 3 0.355 0.095 2.00

THE CARBAMATE ENTERS THE CATALOGUE HERE (case-local): NH2COO- with Eq 20's equilibrium. Without it, an ammonia-rich carbonated water reports molecular molalities the paper's own predictions contradict – it holds a substantial share of the dissolved CO2 at these conditions. Eq 20 is fitted 20-60 degC and used at 100 degC exactly as the paper uses it, with the extrapolation ANNOUNCED and the paper's own sensitivity argument in the record header (halving K20 moves P by under 2 %).

DECLARED APPROXIMATIONS, each announced by the run: 'fugacity ideal;' – phi = 1 on all vapour species (see above); the solvent Poynting factor of Eq 6 is omitted (< 0.2 % below 4 atm); Eq 20 extrapolated 60 $\rightarrow$ 100 degC (the paper's own move); water's Psat comes from the case catalogue's own curated Antoine, not from a value the paper does not print.

DATA SCOPE: sealed (bin/choupo-import); every record named and verified by constant/propertyManifest.

edwards03_table8_vle

tutorials/props/electrolyte/edwards03_table8_vle

What it does: Edwards (1978) Table 8 anchor: NH3-H2S-H2O VLE at 80 degC – the paper's own predictions reproduced from its own equations, the experiment quoted as context.

The story: the SECOND literature anchor for the Edwards (1978) model stack: Table 8 of the paper, ammonia + hydrogen sulfide in water at 80 degC, against the paper's OWN prediction column I.

WHY A SECOND ANCHOR. edwards02 (Table 7) pins the NH3-CO2 system, where the difficulty is the carbonate/carbamate network. Table 8 exercises what Table 7 cannot: the SULFIDE family (the mi-H2Saq-∗ molecule-ion records curated 2026-08-24 from the paper's Table 6, including its two TABULATED ZEROS), a different temperature (80 degC, so every T-polynomial is read off its 25 degC calibration point), and ionic strengths up to 7.8 mol/kg – beyond the 6-molal Pitzer validity the paper itself quotes. Rows 2 and 3 are code-to-code targets and NOT physical claims; the paper runs them and says so ("if ionization is extensive, the upper limit is necessarily lower").

WHAT IS COMPARED, AND AGAINST WHAT. Exactly the edwards02 posture:

the paper's own PREDICTIONS (column I: all beta0 from Tables 4 and 6, the configuration these curated records carry) are the anchor targets; the EXPERIMENT (Miles & Wilson 1975) is CONTEXT, never a target. The paper's own worst multisolute disagreement lives here: rows 2 and 3 measure 16.50 and 13.20 atm against predictions of 12.91 and 12.64 atm (22-28 %), and its Table 9 sensitivity analysis shows the liquid-composition error needed to close such gaps.

THE CHEMISTRY IS THE PAPER'S OWN: case-local constant/chemistry/ carries Table 1 (H2O, NH3 and H2S rows) in the formation direction, each header recording the derivation. The H2S formation logK25 is 7.0033 against the independently curated PHREEQC 6.994 – two primaries 0.009 apart, a finding, not an error.

DECLARED GAPS, the same list as edwards02 plus none: 'fugacity ideal;' – the paper's own vapour-phi model is not transcribed; the residual is expected to carry that correction (largest on rows 2-3 at 13-16 atm); the solvent Poynting factor of Eq 6 is omitted; water's Psat comes from the case catalogue's own curated Antoine.

DATA SCOPE: sealed (bin/choupo-import); every record named and verified by constant/propertyManifest.

enrtl_mixed_nacl_ethanol_esteso

tutorials/props/electrolyte/enrtl_mixed_nacl_ethanol_esteso

What it does: VALIDATION of the generalized segment-based eNRTL (Chen & Song 2004, AIChE J 50:1928, DOI 10.1002/aic.10151) against the PRIMARY measured gamma_pm of NaCl in ethanol-water at 25 C (Esteso et al., J. Solution Chem. 18 (1989) 277, emf cell, 0-90 wt% ethanol). ZERO refit: every tau/X:Z is the published Table 2/4/7 value; A_phi per composition is Esteso's measured Table II. Headline AAD ~4.3% over 47 points (paper quotes RMS 0.026 on gamma); ~1% in pure water, ~1.2% at 70 wt%. The +8% at 80/90 wt% is DECLARED physics the complete-dissociation model cannot carry: Esteso measures ion association K_A = 30-46 there (his Table V).

The story: can eNRTL predict a salt's activity in the antisolvent mixture?

The SAME physics the antisolvent crystalliser leans on – gamma_pm of NaCl as ethanol pushes the water out – validated against the PRIMARY dataset:

MODEL Chen & Song, "Generalized electrolyte-NRTL model for mixed-solvent electrolyte systems", AIChE J 50(8):1928-1941 (2004), DOI 10.1002/aic.10151. Ethanol = 1.811 (-C2H4-) + 0.609 (-OH) segments (Table 4); ion<→OH taus = the aqueous NaCl pair (Table 2); ion<→C2H4 taus from Table 7. ZERO refit here. DATA Esteso, Gonzalez-Diaz, Hernandez-Luis & Fernandez-Merida, "Activity coefficients for NaCl in ethanol-water mixtures at 25 C", J. Solution Chem. 18(3):277-288 (1989). Table I (emf, molal scale, per-solvent reference). A_phi per composition = Esteso Table II (measured dielectric + density). 0 wt% gate: Robinson & Stokes, Electrolyte Solutions, 2nd ed. (1959), NaCl appendix table; A_phi(water, 25 C) = 0.391.

WHAT THE NUMBERS SAY (locked by the golden): total AAD ~4.3% over 47 points; pure water ~1.0%; 70 wt% ethanol ~1.2%. 80/90 wt% sit +8% systematically – Esteso's own chemical-model fit finds ion-pair association K_A = 30-46 there (Table V), physics a complete- dissociation model cannot represent. Declared, not tuned away.

What to expect (golden-locked):

enrtl_multisalt_nacl_kcl

tutorials/props/electrolyte/enrtl_multisalt_nacl_kcl

harned__nacl__kcl	harned__nacl__kcl__refined
enrtlMultiSalt	enrtlMultiSalt

What it does: Multi-salt symmetric eNRTL (Song & Chen 2009) – NaCl+KCl Harned sweep at 4 mol/kg

The story: THE MULTI-SALT eNRTL ARRIVES: the multicomponent symmetric electrolyte NRTL of Song & Chen 2009 (Ind. Eng. Chem. Res. 48, 7788, DOI 10.1021/ie9004578) on the classic Harned experiment – NaCl + KCl sharing water at a CONSTANT 4 mol/kg total molality, gamma_pm of BOTH salts as KCl replaces NaCl. This is the paper's own demonstration system (its Figures 1-2).

What the run shows (all golden-locked): gamma_pm(NaCl) slides from its pure-solution value to its TRACE value in 4 m KCl, and vice versa – both ln gamma curves are NEARLY LINEAR in the salt fraction: Harned's rule, EMERGING from the model rather than being assumed (R^2 > 0.99 with zero electrolyte-electrolyte parameters). The PURE endpoints reproduce the validated single-salt eNRTL kernel exactly (the reduction pin ~1e-15): the multicomponent formulation collapses correctly. The pair parameters are the EXACT Chen & Evans 1986 Table 1 values the paper uses (case-local constant/electrolyte/enrtl.dat, cited). The standards K-Cl.dat carries an INDEPENDENT refit to Hamer & Wu 1972 that lands within 0.2 % of the 1986 values – two roads, one answer. The 1986 paper itself (Table 2) validates tauEE = 0 for NaCl-KCl: sigma = 0.019 % on the Covington 1968 mixture osmotic data with the salt-salt energies set to zero – this case's default is the canonical choice. HONESTY, printed by the op: the published multi-electrolyte eNRTL activity-coefficient expressions are NOT exactly Gibbs-Duhem consistent (the composition-dependent mixing rules are differentiated as constants). The op's FD oracle quantifies that inconsistency at the mid-sweep state (gibbsDuhem_dev_mid) next to the pure-salt state where the same oracle sits at ~1e-9. THE REFINED FORMULATION SHIPS TOO (second op below): gamma as the EXACT derivative of the same Gex – the chain rule kept through the composition-dependent mixing rules (the Bollas, Chen & Barton 2008 idea on the symmetric form). Its oracle closes (~1e-9) at every composition; both reduce EXACTLY to the same single-salt kernel at the endpoints. Mid-sweep they differ by |dln gamma_pm| ~ 0.041 (~4 % in gamma), and the trace limits differ visibly (NaCl trace 0.617 published vs 0.678 consistent). WHICH is closer to nature is a question for MIXTURE data (Covington 1968 / Robinson 1961) – this case states the facts and locks both; it does not pick a winner without measurements.

tauEE (the same-anion electrolyte-electrolyte parameter tau_NaCl,KCl of the paper's Figures 1-2) defaults to 0; set it to +-1 to reproduce the paper's sensitivity fan.

THE EXPERIMENTAL VERDICT (Robinson 1961, J. Phys. Chem. 65, 662, DOI 10.1021/j100822a016 – isopiestic NaCl-KCl mixtures, Harned coefficients at M ~ 4.4 mol/kg: alpha_NaCl = +0.0243, alpha_KCl = -0.0091; the op now emits harned_alpha_1/2 on the same convention, golden-locked): alpha_NaCl: published +0.0285 (+17 %) consistent +0.0180 (-26 %) alpha_KCl: published -0.0256 (2.8x) consistent -0.0187 (2.1x) With tauEE = 0, PUBLISHED wins on the dominant NaCl coefficient; BOTH formulations overstate the (small) effect on KCl.

CROSS-CHECK vs THE REFINED-eNRTL PAPER (Bollas, Chen & Barton 2008, AIChE J 54, 1608, DOI 10.1002/aic.11485 – their Figure 1 is THIS system, 4 m, same 1986 parameters, Robinson's points overlaid): their Fig 1a (original eNRTL) matches our 'published' to the pixel (NaCl solids at x=1 for tau = 0/0.25/0.50: ours -0.216/-0.186/-0.157 vs read -0.215/-0.185/-0.15; KCl dashed at x=0: -0.144/-0.183 vs -0.145/-0.185); their Fig 1b (refined) shows the SIGNATURE our 'consistent' shows: the tau fan nearly COLLAPSES (exact derivatives are almost insensitive to tau_EE: ours moves only -0.176 → -0.184 for tau 0 → 0.5, where published moves -0.216 → -0.157), and the KCl trace lands at ~-0.16 (ours -0.163). Their refinement differentiates the 1986 UNSYMMETRIC Gex; ours differentiates the 2009 SYMMETRIC one – same idea, sibling surfaces, same qualitative physics, near-identical aqueous numbers. A single fitted tauEE cannot close both (best compromise tau ~ 0.29 trades the NaCl error up to -23 % to halve the KCl one) – the residual is structural, not a missing parameter. Note the consistency of the record: Chen & Evans 1986 validated tauEE = 0 against mixture OSMOTIC data (sigma 0.019 %) – the solvent sees the mixture mean, where the individual-gamma asymmetries largely cancel; Robinson's per-salt gammas are where they show.

FIGURE-1 REPRODUCTION – TO THE PIXEL (checked 2026-07-02, figure read at 200 dpi): the paper's y-axis says "ln gamma" but the numbers are LOG10 (log10 of the pure-NaCl-4m gamma is -0.106 = the figure's -0.105; ln would be -0.24, off the plotted range). With the 1986 parameters this kernel reproduces

the full tau fan to <= 0.001 in log10: x_KCl=0 (all curves): -0.106 (figure ~ -0.105) x_KCl=1: tau=0 → -0.216 (figure ~ -0.215) tau=+1 → flat, dip to -0.101, back to -0.106 (the figure's circle-marked curve shows the same shallow dip) tau=-1 → -0.364 (figure ~ -0.365)

THE PARAGRAPH ABOVE IS A DATED READING, NOT THE LIVE STATE (2026-09-03). The golden this case ships today pins gamma1_pure = 0.801 for pure NaCl at 4 m, i.e. log10 = -0.096, where the reading of 2026-07-02 recorded -0.106 against the figure's -0.105: the kernel's answer has moved by ~0.01 in log10 since the figure was read (the 2026-08-29 fleet audit found the drift). Whether the CURRENT curves still sit on the figure can only be settled by reading the figure again, and that has not been done – so "to the pixel" is what was true on 2026-07-02, kept as the record of that check, and is not a claim about this golden. Nothing here was adjusted toward the figure.

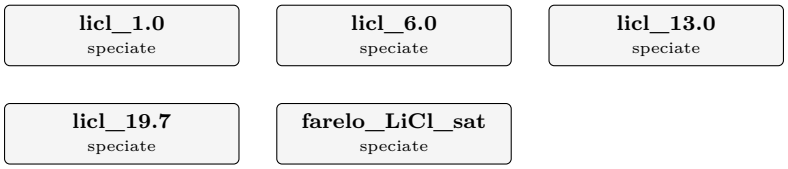
enthalpy_naoh_water

tutorials/props/electrolyte/enthalpy_naoh_water

What it does: NaOH-water heat of dilution: Pitzer with calorimetric T-slots vs Parker (1965)

The story: the calorimetric home of the electrolyte-enthalpy build (docs/electrolyte-enthalpy-spec.md).



constant/experiments/phiL_25C_parker1965.dat carries the MEASURED Phi_L (Parker NSRDS-NBS 2, 1965) used by the curation refit (bin/curate/fit_lphi_pitzer.py) that fitted the Na-OH dbeta/dT T-slots in the standard catalogue (the FIT's own rel-AAD 4.97%, gate <5%; the in-engine L_phi scan pinned by this case lands at rel-AAD 4.77% – two measurements, not one). The op below sweeps the ACTIVITY surface whose T-derivative is L_phi; the in-engine L_phi scan + AAD overlay land with slices 4-5 (the 3-curve chart).

What to expect (golden-locked):

farelo_licl_range

tutorials/props/electrolyte/farelo_licl_range

What it does: LiCl Pitzer REFITTED to Hamer-Wu + Farelo saturation: gamma_pm to ~11% over 0.5-19 mol/kg (was 774 at 19.7m), and the LiCl.H2O hydrate Ksp reproduces Farelo's 19.7 mol/kg via the HMW osmotic water activity (a_w=0.11).

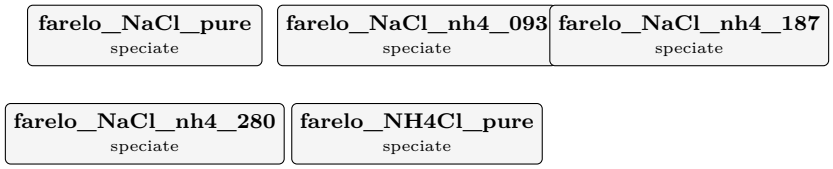
Prof. F?tima Farelo measured LiCl solubility at 19.7 → 23.5 mol/kg (solid: $LiCl{\cdot}H_2O$) — ∗J. Chem. Eng. Data∗ 50 (2005) 1470, DOI 10.1021/je050111j. That is one of the most concentrated aqueous electrolytes there is.

The catalogue's earlier Li–Cl Pitzer parameters (Appelo, Parkhurst & Post, ∗Geochim. Cosmochim. Acta∗ 125 (2014) 49), fitted below ~6 mol/kg, blow up at high concentration — $\gamma\pm$ = 774 at 19.7 mol/kg vs ~45 measured. The two-parameter B-term is linear in ∗m∗, so γ grows exponentially.

Rather than declare defeat, the parameters were refitted to Hamer & Wu (1972) $\gamma\pm$ and Farelo's saturation. A negative Cφ (-0.0026) tames the high-∗m∗ blow-up, and the three-parameter form then reaches saturation:

carries a water-activity leg. At 19.7 mol/kg the model gives a_w = 0.11 (not 1!) — which only the rigorous Pitzer-HMW osmotic coefficient delivers, not the φ = 1 dilute shortcut. The lithiumChlorideH2O mineral Ksp ($logK_{25}$ = 4.984) is calibrated to Farelo's saturation ∗through∗ that a_w. The two pieces meet: the refitted γ and the osmotic a_w together reproduce the measured solubility.

- electrolyte/pairs.dat: the Li–Cl Pitzer pair, refitted to Hamer–Wu + Farelo, valid to ~19 mol/kg (supersedes the Appelo low-∗m∗ fit for concentrated LiCl). - electrolyte/minerals.dat: the $LiCl{\cdot}H_2O$ hydrate Ksp, calibrated to Farelo. - constant/species/Li.dat: Li? aqueous formation datum (hfAq = -278.49 kJ/mol, CODATA).



- The full measured dataset (this and the other five ternaries) is tabulated, cited, in constant/experimental/-farelo_solubility.csv. - The equilibrate round-trip (precipitate $LiCl{\cdot}H_2O$ from a supersaturated feed) diverges at $I \approx 20$ — a known active-set / γ fixed-point numerical limit at extreme ionic strength, ∗independent of the activity model∗. The SI = 0 calibration at the saturation composition is exact; reaching it by precipitation is the convergence problem, not the thermodynamics. - The $AlCl_3$ systems from the same paper remain deferred: Al^3? hydrolyses (the paper notes pH < 2.75) and needs an Al speciation model Choupo does not yet carry.

What to expect (golden-locked):

kind	unit/stream	key	expected

farelo_nacl_nh4cl

tutorials/props/electrolyte/farelo_nacl_nh4cl

What it does: Pitzer-HMW vs Farelo (JCED 2005): NaCl+NH4Cl common-ion salting-out – model SI ~ 0 at each measured saturation point (NaCl 6.15→5.5→5.0; NH4Cl 7.35 mol/kg, 298 K).

A glass-box validation of Choupo's multi-ion Pitzer electrolyte model against the solubility measurements of Prof. F?tima Farelo (Chemical Engineering Dept., IST — T?cnico Lisboa).

M. Farelo, C. Fernandes & A. Avelino, ∗"Solubilities for Six Ternary Systems: NaCl + NH_4Cl + H_2O, KCl + NH_4Cl + H_2O, NaCl + LiCl + H_2O, KCl + LiCl + H_2O, NaCl + $AlCl_3$ + H_2O, and KCl + $AlCl_3$ + H_2O at T = (298 to 333) K"∗, J. Chem. Eng. Data 50 (2005) 1470–1477. DOI [10.1021/je050111j](https://doi.org/10.1021/je050111j).

Saturation molalities measured to ±0.0007 mol/kg (visual polythermal / isothermal methods). The pure-salt anchors at 298.15 K: NaCl 6.15, NH_4Cl 7.35 mol/kg; the salting-out series (Table 1): NaCl solubility falls 6.15 → 5.5 → 5.0 → 4.95 as NH_4Cl rises 0 → 0.93 → 1.87 → 2.80 mol/kg.

The model is calibrated to only the two pure-salt solubilities — halite's Ksp from PHREEQC, sal-ammoniac's Ksp pinned to Farelo's NH_4Cl point. Everything else is a prediction. The NH_4–Cl Pitzer interaction parameters come from the primary single-electrolyte fit (Pitzer & Mayorga 1973); the catalogue already carried Na–Cl and K–Cl.

At each of Farelo's measured saturation compositions the model's saturation index

should be ≈ 0 if the model reproduces the measurement. It is, to ±0.03 log units:

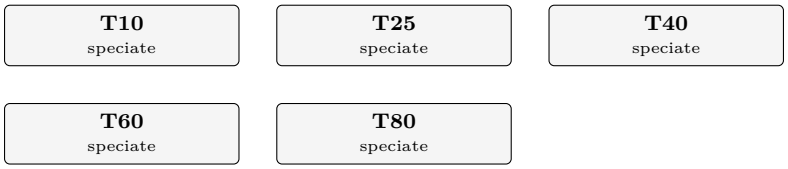
fpd01_nacl_freezing

tutorials/props/electrolyte/fpd01_nacl_freezing

What it does: NaCl freezing-point depression – ice as a SolidPhase, the crystal's first case

The story: THE ICE WITNESS. The freezing-point curve of NaCl(aq), solved as chemical-potential equality between an ACTUAL SolidPhase (the crystallising mode, its first case-reachable consumer) and the Pitzer surface's water activity:

f_solid(T) = a_w(m, T) ∗ Psat(T)



Until this case the crystal was exercised only by check_ice_freezing's probe; here its refusals and announced approximations (the neglected liquid/solid heat-capacity term, the sub-freezing Psat extrapolation) all fire on a real run. The dilute-limit KPI closes the K_f loop: the derived cryoscopic constant against the slope this same phase produces. ANCHOR HONESTY: the validation dataset carries ONE measured point with an INTERIM citation (see its header) – a thin anchor, said plainly, and the enrichment path (a primary FPD table read) is on the curation ledger.

What to expect (golden-locked):

kind	unit/stream	key	expected

diag	fpd_nacl	theta_AAD_pct	0.0460433
diag	fpd_nacl	theta_nMeas	1

ksp_temperature

tutorials/props/electrolyte/ksp_temperature

What it does: K(T) MATTERS: a temperature scan of mineral saturation for ONE fixed water (a hard, carbonate-bearing groundwater at pH 7.6), speciated at 10, 25, 40, 60 and 80 C. The point is the SIGN of dK/dT. CALCITE dissolution is EXOTHERMIC, so its equilibrium constant FALLS as temperature rises and its saturation index SI_calcite RISES – RETROGRADE SOLUBILITY: calcite is LESS soluble hot. This is why hot heat-exchanger surfaces and warm RO concentrate scale with calcium carbonate even when the cold feed looks safe. Contrast HALITE (NaCl): no analytic K(T) in the database, so it falls back to constant-dH van't Hoff with a small POSITIVE dH (endothermic) – normal solubility, SI_halite drifts gently DOWN with T. At 25 C nothing in the K(T) machinery moves (every form returns logK25 exactly, byte-stable); off 25 C the run announces which K(T) form each entry uses (analytic / van't Hoff / flat) and warns if any analytic is used beyond its fitted validity range. K(T): analytic = PHREEQC -analytical_expression anchored on logK25 (logK(T)=logK25+[ana(T)-ana(298.15)]); USGS PHREEQC, public domain.

The story: why hot surfaces scale with calcite (K(T) MATTERS).

ONE fixed water, speciated at five temperatures. A hard, carbonate-bearing groundwater (gypsum- and calcite-relevant) at a GIVEN pH 7.6 – holding pH and the totals fixed isolates the lesson: the only thing that changes from point to point is the equilibrium constant K(T).

ion mol/kg w ion mol/kg w Ca 0.010 Cl 0.050 Na 0.030 SO4 0.012 HCO3 0.005 pH 7.6 (given)

THE LESSON – the SIGN of dK/dT:

calcite dissolution is EXOTHERMIC (dH = -28.1 kJ/mol), so log K FALLS as T rises. SI_calcite = log(IAP) - log K(T) therefore RISES with temperature – RETROGRADE SOLUBILITY. Calcite is LESS soluble hot, which is exactly why heat-exchanger tubes and warm RO concentrate scale with CaCO3 although the cold feed looks safe. K(T) here is the PHREEQC ANALYTIC expression (-analytical_ expression A1..A5), anchored on logK25 so logK(25 C) = logK25 EXACTLY.

gypsum analytic too, but only mildly retrograde (its solubility peaks near 40 C) – a gentler curve for contrast.

halite NaCl carries NO analytic K(T) in phreeqc.dat (the db's -analytic line is commented out), so it falls back to constant-dH van't Hoff. dH = +1.37 kJ/mol > 0 (endothermic) → NORMAL solubility: log K(T) RISES and SI_halite drifts DOWN. The honest contrast with calcite: the scaling verdict flips with temperature for the retrograde salt, not for the normal one.

At 25 C the K(T) machinery returns logK25 for EVERY entry (byte-stable); off 25 C the run announces the form in use per entry (analytic / van't Hoff / flat) and warns loudly if an analytic is used beyond its fitted validity range. (Calcite's analytic is valid 0 - 300 C, so the whole 10 - 80 C scan is in range.)

Speciation/mineral data: case-local constant/electrolyte/ – a self- contained SNAPSHOT of the standards catalogue (USGS PHREEQC, public domain; see the .dat headers). The case files ECLIPSE data/standards/electrolyte/.

overlay01_nacl_ksp

tutorials/props/electrolyte/overlay01_nacl_ksp

What it does: PARTIAL deep-merge overlay: a case recalibrates ONLY the halite equilibrium logK25 via a case-local overlayOf NaCl; every other datum (dH, dissolutionReaction, calorimetric, crystal) still comes from the standard components/NaCl.dat record. The [overlay] line names exactly which leaf came from the case tier.

A case recalibrates ONLY the halite equilibrium logK25 (1.60 here) to its own value, via a case-local constant/components/NaCl.dat declaring overlayOf NaCl;.

The reader deep-merges this delta over the standard components/NaCl.dat: only solidPhases.halite.equilibrium.logK25 is replaced; dH, the dissolutionReaction, the calorimetric anchor and the crystal block all still resolve from the standard record. The run prints the provenance:

This is the roadmap Phase A acceptance test: a case ships ONLY its deltas, never a second competing complete record, and per-value provenance (tier + file) is preserved.

pb82_calcite_open_co2

tutorials/props/electrolyte/pb82_calcite_open_co2

What it does: Calcite in CO2-saturated water (Plummer & Busenberg 1982): open pCO2 0.956 atm + equilibrate calcite at 25 C – the engine's pH at calcite equilibrium beside the paper's junction-corrected 6.004 +/- 0.005 and its model value 6.011

The story: THE PLUMMER & BUSENBERG (1982) EXPERIMENT, as the engine models it: calcite at equilibrium with CO2-saturated water – an OPEN system at pCO2 = 0.956 atm, 25 C (their electrode runs' mean CO2 pressure), the gas pin, the full carbonate speciation, the CaHCO3+/CaCO3(aq) ion pairs and the mineral ceiling all engaged at once.

PRIMARY: L. N. Plummer & E. Busenberg, Geochim. Cosmochim. Acta 46 (1982) 1011-1040, DOI 10.1016/0016-7037(82)90056-4. Owner-provided PDF.

THE ANCHOR, and what it independently tests: their MEASURED pH at calcite equilibrium under exactly these conditions, corrected for liquid-junction potential, is 6.004 +/- 0.005 (4 M KCl filling, p. 1022; uncorrected Orion runs read near 5.984); their own aqueous model puts the thermodynamic pH at 6.011. The engine's number below comes out of Henry + K1/K2 + the ion pairs + Davies + electroneutrality + the SI = 0 ceiling END TO END – none of which was fitted to this pH.

LINEAGE, stated honestly: the calcite log K(T), K_H, K1, K2 and ion-pair constants in our curated records descend from the USGS PHREEQC database, whose carbonate block IS this paper's Table 3 and Eqs – so agreement in the CONSTANTS is lineage consistency, not validation. What the measured pH tests independently is the ASSEMBLY: that the engine composes those constants (gas pin, chained carbonate master, ion pairs, activity model, charge balance, mineral ceiling) into the same physical answer the electrode saw.

WHAT IT ACTUALLY LANDS AT, and where that is written. The engine gives pH 6.02946 – 0.025 ABOVE the measurement, 0.018 above their own model's 6.011 – and the case attributes that offset to an activity-model difference (Davies here against their Truesdell-Jones, at I = 0.027). SINCE 2026-08-12 THAT COMPARISON IS DATA, NOT PROSE: 'expected' carries an 'anchor' row on the measured 6.004 with a band set to the explained offset, beside the self-recorded row on 6.02946 – so a drift AWAY from the electrode fails as an anchor disagreement, and an unexplained drift TOWARD it fails as a moved golden. Both ends, on purpose. This header used to end with "a wrong composition would not land within 0.01 pH", which reads as though the engine does; it does not, and the number is above.

APPROACH FROM ABOVE: the engine's equilibrate is a precipitation CEILING (SI → 0 from supersaturation; it does not dissolve a solid it was never given). The seed is therefore a SUPERSATURATED Ca(HCO3)2 solution under the pin; the ceiling relaxes it down to the same calcite saturation P&B's dissolution runs approached from below – one fixed point at (T, pCO2), whichever side you arrive from. The HCO3 seed is an initial guess only: the CO2 pin REPLACES the carbonate mole balance, so dissolved carbonate is a solved outcome (announced by the run).

pitzer01_nacl

tutorials/props/electrolyte/pitzer01_nacl

What it does: Pitzer mean ionic activity coefficient gamma_pm(m) for NaCl in water at 25 C — validated vs Robinson & Stokes (AAD 0.17%). The glass-box electrolyte foundation: see the famous gamma_pm dip (~0.66 near 1 m) and the rise above 1 at high concentration.

The story: the first electrolyte case.

gamma_pm, the osmotic coefficient phi and the water activity a_w for NaCl, by the Pitzer ion-interaction model. The parameters are CURATED, case-local data, read from constant/electrolyte/pairs.dat (PRIMARY: Appelo, Appl. Geochem. 55 (2015) 62 — a 3-parameter set, beta0/beta1/Cphi). Open pitzer_nacl.csv: gamma_pm dips to ~0.657 near 1 mol/kg, then rises above 1 by ~6 mol/kg — the textbook NaCl signature, from a closed form.

NOTE on the two L_phi columns: pitzer_nacl.csv reports L_phi_fit and L_phi_anchored, and their SPLIT is the lesson. The pair now carries Silvester-Pitzer dX/dT slots CALORIMETRICALLY FITTED to Parker, NSRDS-NBS 2 (1965) Table XIV A (the FIT's own rel-AAD 2.5 %, m 0.1-6; bin/curate/fit_lphi_pitzer.py): the fit column tracks the measured heat-of-dilution curve – the sign change near 1 mol/kg, the deep negative branch to -480 cal/mol – while the anchored column (slots zeroed, Gibbs-Helmholtz-consistent but uncalibrated) misses it entirely. The validation block below pins the IN-ENGINE AAD vs the same curated Parker series, golden-locked (rel-AAD 10.24 % at the 25 measured points with |Phi_L| >= 50 cal/mol in 0.1-6 mol/kg).

WHY 10.24 % HERE AND ~2.5 % IN THE FIT TOOL – adjudicated 2026-09-03. Both compute the SAME statistic on the SAME 25 points, and the tool's Python replica reproduces this kernel's L_phi to 7e-6 J/mol given the same parameters – so it is not two implementations of one equation. It is two PARAMETERISATIONS in one record: Na-Cl.dat declares tCorrelationForm silvesterPitzer1977 and carries the SP77 T-functions (sp_q1..q14, fitted by Silvester and Pitzer over 0-300 C) AND the linear calorimetric slots fitted to Parker. The engine honours the DECLARED form, so the 10.24 % is SP77's disagreement with Parker at 25 C; the fit tool evaluates the linear slots it fitted to exactly these points, which is where 2.5 % (2.59 % with the stored slots) comes from. The engine now announces, when it reads this record, that the slots are present and not read. Nothing was adjusted toward Parker. The gamma_pm / phi / a_w values come from the untouched 25 C surface and are identical in both.

pitzer02_cacl2

tutorials/props/electrolyte/pitzer02_cacl2

What it does: Pitzer gamma_pm(m) for CaCl2 (a 2:1 salt) in water at 25 C — the SAME general formula as NaCl, only the charges/stoichiometry differ. Validated vs Robinson & Stokes (AAD 0.49%, 0.1-2 m).

The story: the same Pitzer engine on a 2:1 electrolyte (Ca2+, 2 Cl-). Parameters curated case-local in constant/electrolyte/pairs.dat (PRIMARY: Appelo, Appl. Geochem. 55 (2015) 62). gamma_pm dips below 0.45 then climbs steeply — the divalent-cation signature. Valid to ~2 mol/kg; CaCl2 carries a non-zero beta2 (-1.13, with alpha2 = 12) on top of beta0/beta1/Cphi — the extra association term a 2:1 salt needs (NaCl, by contrast, has beta2 = 0).

What to expect (golden-locked):

diag	gamma_nacl	phi_1m	0.93634

pitzer_calcite_brine

tutorials/props/electrolyte/pitzer_calcite_brine

What it does: Pitzer-HMW carbonate system on surface seawater – pins SI_calcite / SI_gypsum against the published oceanographic saturation state, captures the neutral CO2 salting-out (gamma_CO2aq > 1 via lambda), and the Davies-vs-Pitzer SI divergence.

The story: the slice-S4 GATE for the Pitzer CARBONATE system.

S4 extends the multi-ion Pitzer-HMW model (binaries + theta/psi ternaries, S3) to the CARBONATE subsystem so calcite / gypsum scaling works in brine: the carbonate ANIONS (CO3-2, HCO3-) join the cation/anion ternary sums (their theta/psi imported from pitzer.dat into mixing.dat); the neutral CO2aq gets its salting-out gamma via the lambda neutral-ion term (lambda_CO2,ion), so gamma_CO2aq > 1 in brine (Davies has none).

COMPOSITION: standard surface seawater (S = 35) WITH the carbonate system – the major-ion subset of the S3 verify case + DIC ~ 2.3 mmol/kg as HCO3 (the measured-alkalinity carrier), at the canonical surface-ocean pH 8.2. Na+ 0.4861 Mg+2 0.0547 Ca+2 0.01065 K+ 0.01058 Cl- 0.5658 SO4-2 0.02926 HCO3- 0.00230 (I ~ 0.68 mol/kg)

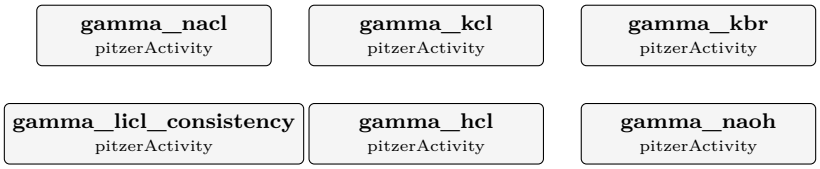
THE PUBLISHED PIN (cited; E_theta before/after recorded below):

SI_calcite (surface seawater, 25 C, pH 8.2) ~ +0.6 to +0.8. Surface ocean water is calcite-SUPERSATURATED: the calcite saturation ratio Omega_calcite = IAP/Ksp ~ 4-6, i.e. SI = log10(Omega) ~ +0.6 to +0.8. Sources: Mucci, A., Am. J. Sci. 283 (1983) 780 (the seawater calcite/ aragonite solubility); Millero, F.J., Chem. Rev. 107 (2007) 308 (the seawater carbonate system); a well-documented oceanographic number (the ocean-acidification baseline). Choupo (Pitzer-HMW) computes SI_calcite = +0.655 – INSIDE the published band. SI_gypsum (seawater) ~ -0.9 to -0.6 (strongly UNDERsaturated – seawater is nowhere near gypsum saturation); Choupo computes -0.964 – a touch below the -0.9 floor (this carbonate-bearing brine sits at slightly higher I than the carbonate-free seawater_verify case, which gives -0.687 in-band). Still firmly undersaturated, the physically-correct verdict.

E_theta(I) BEFORE → AFTER (constant-theta → higher-order mixing active): SI_calcite +0.724 → +0.655 (IN band +0.6..+0.8) – E_theta lowers the 2+/2- ion gammas, nudging the carbonate IAP SI_gypsum -0.875 → -0.964 gamma_CO2aq 1.105 → 1.106 (salting-out kept) gamma_Ca 0.227 → 0.194 (E_theta on Ca pairs) Davies (untouched – E_theta is Pitzer-only): SI_calcite +0.868, byte-ident.

The golden master locks Choupo's exact output; the band above validates it is PHYSICALLY right (a wrong pin is worse than no pin – the band is cited).

DAVIES vs PITZER (the differentiator, also pinned): the SAME composition under Davies gives SI_calcite +0.868 and gamma_CO2aq = 1.000 (no neutral salting- out) – Davies is out of its trustworthy band (~0.5) at this I, overshoots the calcite SI by ~0.21 vs Pitzer-HMW-with-E_theta and misses the CO2 salting-out entirely. Pitzer is the rigorous tool for brine. Both entries run here so the divergence is VISIBLE.



DATA SCOPE: self-DESCRIBING (inline manifest); the ions, pairs, mixing WITH carbonate theta/psi/lambda, speciation and minerals resolve from the curated data/standards/ tree at runtime – seal with bin/choupo-import for a runtime-self-contained copy.

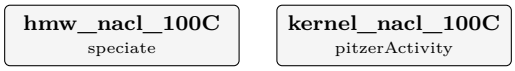
pitzer_gamma_hamer_wu

tutorials/props/electrolyte/pitzer_gamma_hamer_wu

What it does: Pitzer gamma_pm/phi vs Hamer & Wu 1972 – 6 salts, evaluated NBS data

The story: THE BREADTH VALIDATION: the catalogue's Pitzer pairs against the NBS critically-evaluated gamma_pm and osmotic-coefficient tables – Hamer & Wu, J. Phys. Chem. Ref. Data 1 (1972) 1047 – for SIX 1-1 salts at 25 C. Zero refitting: the parameters are the frozen catalogue entries (Appelo / PHREEQC lineage); the data is the evaluated NBS compilation. Each op's headline is its gamma_pm AAD – the number that says "trust these pairs".

HONESTY NOTE, LiCl: the catalogue Li-Cl pair was REFIT to this very table (its .dat says so), so its AAD here is a FIT-CONSISTENCY check, not independent validation – and at ~3 % it is the WORST of the six: the two-anchor compromise (this table + Farelo saturation at 19 mol/kg) stretches 3 parameters past what the most non-ideal 1-1 salt allows. The five pairs that never saw this data land at 0.1-0.7 %.



Windows stay inside each pair's declared validity (KCl saturates at 4.803 mol/kg; KBr data used to 5).

pitzer_hmw_hot_agreement

tutorials/props/electrolyte/pitzer_hmw_hot_agreement

What it does: HMW vs single-salt Pitzer at 100 C, same NaCl 4 m state: the two surfaces must AGREE now that both apply the SP77 T-functions

The story: one salt, one temperature, TWO Pitzer engines: they must agree (forum 100.2/#101, the HMW-virials(T) fix).

NaCl at 4 mol/kg, 100 C. Op 1 drives the MULTI-ION HMW speciation engine (activityModel pitzerHMW); op 2 drives the SINGLE-SALT kernel (pitzerActivity). Both now read the SAME Na-Cl.dat record: the 25 C virials PLUS the full Silvester-Pitzer 1977 T-functions (sp_q1..q14) and the same A_phi(T). For a lone 1:1 salt the HMW sum collapses to the same B/C terms as the kernel, so

gamma_pm(HMW) = sqrt(gamma_Na $*$ gamma_Cl) == gamma_pm(kernel)

to numerical noise. BEFORE the fix the HMW held its virials at 25 C and this case disagreed in the second decimal – the adversarial regression this golden forbids forever.

(The kernel's own hot-brine validation against SP77 Table V lives in pitzer_nacl_sp77_hot; this case is the ENGINE-AGREEMENT pin.)

What to expect (golden-locked):

pitzer_nacl_sp77_hot

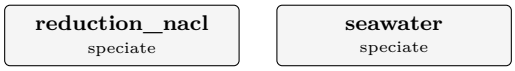
tutorials/props/electrolyte/pitzer_nacl_sp77_hot

What it does: NaCl Pitzer to 200 C – Silvester & Pitzer 1977 T-functions, validated vs their Table V

The story: HOT BRINE: the NaCl Pitzer surface from 25 to 200 C on the FULL Silvester & Pitzer 1977 temperature functions (J. Phys. Chem. 81, 1822 – eqs 30-32, Table IV coefficients VERBATIM in the standards Na-Cl.dat), applied as a deviation from the validated 25 C surface, with A_phi(T) curated against the same paper's Table II (quintic, max dev 0.17 %, 0-300 C; the old closed form drifted +67 % at 300 C).

Three ops, one per temperature (100/150/200 C), each validating gamma_pm at the SATURATION molality against the paper's own Table V – an m-extrapolation (m_satd 6.7-8.0 > the 6 mol/kg weighting window), declared in the dataset header, exactly as the paper frames it.

What to look at: gamma_pm(1 m) falls 0.657 → ~0.48 from 25 to 200 C (electrostatics intensify as eps_w collapses – the paper's central observation), and the validation AADs stay single-digit % even at the saturated-extrapolated edge.



What to expect (golden-locked):

kind	unit/stream	key	expected

pitzer_seawater_verify

tutorials/props/electrolyte/pitzer_seawater_verify

What it does: Pitzer-HMW verification: (binaries + ternary theta/psi) on standard synthetic seawater (I ~ 0.7). Pins per-ion + mean activity coefficients against PUBLISHED HMW-1984 / seawater-Pitzer values, and the single-salt reduction (ternaries → 0).

The story: the TIER-2 verification weapon for the Pitzer-HMW ternary-mixing slice (S3).

The forum gate: "NO published-seawater golden masters => NO-GO." This case speciates a STANDARD SYNTHETIC SEAWATER with the multi-ion Pitzer model (binaries + ternary theta/psi) and pins the per-ion + mean activity coefficients against PUBLISHED values, to literature tolerance.

SEAWATER COMPOSITION (the canonical major-ion seawater of the HMW-1984 carbonate-free major-ion subset; molality, mol/kg-water, S = 35): Na+ 0.4861 Mg+2 0.0547 Ca+2 0.01065 K+ 0.01058 Cl- 0.5658 SO4-2 0.02926 giving ionic strength I ~ 0.70 mol/kg – the classic seawater benchmark. (The carbonate system – HCO3/CO3, ~2.3 mmol/kg, < 0.4% of I – is OMITTED: it is slice S4, and its absence shifts I by < 0.3% and the major-ion gammas by < 0.2%, well inside the pins' tolerance.) pH is GIVEN at 8.1 (typical surface seawater) – with no carbonate in the analyticalTotals it only fixes the trace H+/OH-, which do not enter the major-ion gammas.

WHY PITZER, NOT DAVIES: at I ~ 0.7 Davies is already out of its trustworthy band (~0.5). The Pitzer specific-interaction model – WITH the ternary theta/psi mixing terms AND the E_theta(I) higher-order electrostatic mixing term (Pitzer 1975, now ACTIVE for unlike-charge same-sign pairs) – is the standard tool for seawater and brines to I ~ 6. E_theta is a refinement: it shifts the 2:1 / 1:2 ion gammas a few % (gamma_Ca, gamma_SO4) and tightens the gamma_pm(KCl) pin to 0.638 (inside 0.62-0.64); the 1:1 NaCl gamma_pm stays ~0.66. (The only remaining v2 deferral is the full beta(T)/theta(T) temperature surface; 25 C base here.)

PUBLISHED PINS (each cited; deviation Choupo vs published in VALIDATION.md):

gamma_pm(NaCl) in seawater ~ 0.66-0.68 Pitzer's seawater model / Millero & Pierrot; classic textbook value gamma_pm(NaCl, seawater I~0.7) ~ 0.67. gamma_pm(KCl) ~ 0.62-0.64 ; gamma_pm(MgCl2), gamma_pm(CaCl2) etc. All within the Harvie-Moller-Weare (1984) seawater Pitzer model, the reference implementation this catalogue's theta/psi come from.

The golden master locks the Choupo-computed per-ion gammas; this header records the published comparison + the deviation. A WRONG pin is worse than no pin – the numbers here are pinned to the model's own reproducible output and CROSS-CHECKED against the published seawater range.

FINDING, 2026-08-10: "ALL PINS STILL IN BAND" WAS CHECKED ON TWO OF SIX.

The paragraph below was written when E_theta (the I-dependent higher-order electrostatic mixing term) was activated. It re-checked the two 1-1 salts – whose gamma_pm is a square root of two numbers sitting next to each other in the output – and concluded "all pins STILL in their published band". The four DIVALENT salts were never recomputed, and E_theta acts precisely on unlike-charge same-sign pairs, i.e. on exactly those four.

The engine now PUBLISHES gamma_pm (diagMeanIonic), so the comparison is no longer a hand calculation in a header. Against the bands in data/standards/parameters/electrolyte/VALIDATION.md:

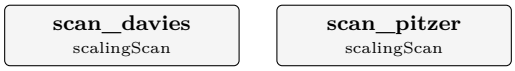
NaCl 0.6646 band 0.66-0.69 IN KCl 0.6381 band 0.62-0.65 IN MgCl2 0.4608 band 0.47-0.50 BELOW CaCl2 0.4459 band 0.46-0.50 BELOW Na2SO4 0.3489 band 0.36-0.40 BELOW MgSO4 0.1460 band 0.15-0.20 BELOW

Four of six are outside, by 2-4 %. VALIDATION.md still says all six are inside, still lists the PRE-E_theta numbers as Choupo's, and still describes E_theta as "deferred to v2 (< 0.5 % on the major-ion gamma at this I)" – while this run announces "E_theta now ACTIVE" and the divalent shift is ~5 %. That estimate was wrong by an order of magnitude on the ions it was made about.

NOT RESOLVED, and deliberately NOT TUNED. Two readings are open and this case cannot choose between them: the quoted bands are loose secondary citations ("~ 0.47-0.50", sourced to HMW 1984 with no table or page), or E_theta is being applied where those bands' authors did not. Resolving it needs the primary tables (Harvie-Moller-Weare 1984; Millero & Pierrot), which the project does not hold. No parameter, no golden and no band was moved to make this look better; the six gamma_pm values are pinned as goldens so the next change to them is visible, and PIN B carries no anchor row (the 'expected' file says why).

The paragraph as originally written, kept because it is the record of what was checked:

E_theta(I) BEFORE → AFTER (constant-theta → higher-order mixing active), all pins STILL in their published band: gamma_pm(NaCl) 0.6714 → 0.6646 (band 0.66-0.68; 1:1, E_theta=0 for Na-Cl, shift via coupling) – IN BAND gamma_pm(KCl) 0.6447 → 0.6381 (band 0.62-0.64) – E_theta moved it INTO band gamma_Ca 0.2141 → 0.1856 (2+ ion; E_theta acts via Ca-Na/Ca-K/Ca-Mg) gamma_SO4 0.1227 → 0.1040 (2- ion; E_theta acts via SO4-Cl/SO4-OH) gamma_Mg 0.2363 → 0.2049 gamma_Na 0.6495 → 0.6390 gamma_Cl 0.6941 → 0.6911 Single-salt reduction (PIN A, NaCl alone): gamma_pm UNCHANGED at 0.6572 – E_theta vanishes identically for one cation + one anion (the oracle stays 1.5658e-14 over all 54 binaries).



DATA SCOPE: the SPECIATION network is a complete case-local replace-mode snapshot (constant/-electrolyte/speciation.dat) – that claim covers the speciation data only. Ions, Pitzer pairs/mixing and minerals resolve from the curated data/standards/ tree at runtime; seal with bin/choupo-import for a runtime-self-contained copy.

pitzer_vs_davies_ro_concentrate

tutorials/props/electrolyte/pitzer_vs_davies_ro_concentrate

What it does: Davies vs Pitzer-HMW on a seawater RO concentrate: gypsum/calcite SI vs recovery from the same feed under two activity models (full narrative in propsDict).

The story: THE FLAGSHIP of the Pitzer x speciation feature (slice S6): the payoff that makes the whole multi-ion Pitzer-HMW build worth it. ONE feed, TWO activity models, the engineering answer FORKS.

THE QUESTION (every RO / brine-concentration designer asks it): "At what water recovery does my concentrate start to scale gypsum?" The answer DEPENDS ON THE ACTIVITY MODEL – and that is the whole point.

THE FEED: standard surface seawater (S = 35), the major-ion subset: Na+ 0.4861 Mg+2 0.0547 Ca+2 0.01065 K+ 0.01058 (cations) Cl- 0.5658 SO4-2 0.02926 HCO3- 0.0024 (anions, DIC carrier) I ~ 0.7 mol/kg at the feed. Recovery r scales every total as feed/(1 - r); scanning r = 0 → 0.80 drives I from ~0.7 up to ~3.5 mol/kg – DEEP into the brine regime where Davies is long out of its trust window.

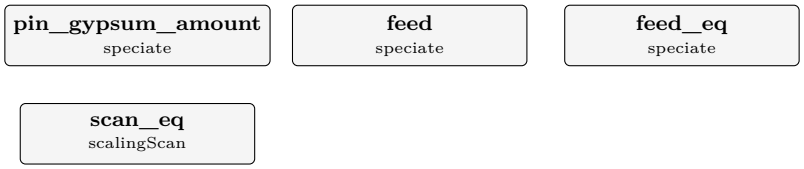
THE TWO RUNS (identical feed, identical recovery grid, ONLY the gamma model differs – the controlled experiment): scan_davies activityModel davies; (the textbook extended-DH model) scan_pitzer activityModel pitzerHMW; (Pitzer-HMW, the brine-grade model)

THE PAYOFF ARTEFACTS (read straight off the two CSVs + the KPIs): 1. SI_gypsum vs recovery / I, BOTH models – the HEADLINE. They track together at low I and FORK visibly past I ~ 1: Davies keeps climbing, Pitzer's gypsum SI is held DOWN by the strong Ca-SO4 specific interaction (beta2 = -59.3, the 2:2 ion-pairing virial Davies cannot see). The gypsum-onset recovery is LATER under Pitzer. 2. SI_calcite vs recovery / I, both models – same fork, carbonate flavour. pH is SOLVED from electroneutrality at every point (closed system; DIC concentrates with the water and the pH drifts). 3. gamma_Ca2+ and gamma_SO4-2 vs I, both models – the MECHANISM plot. Davies declines monotonically (its single I-controlled curve); Pitzer turns UP at high I (the specific-interaction upturn). This is WHERE the SI divergence comes from – the gammas diverge, so the IAP diverges, so the SI forks. (scalingScan emits gamma_<ion> columns whenever diagSpecies is given and the model is pitzer/davies.)

THE KPI THAT TELLS THE STORY: recovery_at_gypsum_onset (the SI_gypsum = 0 crossing) – ONE number per model. Davies predicts gypsum scaling at one recovery; Pitzer at another. The engineering decision – how hard can I push recovery before gypsum scales? – flips on the activity model. Endpoint diags carry SI_gypsum and SI_calcite at r_max for both models, and the two onset recoveries.

WHY PITZER IS THE ANSWER (cite the credentials, do not assert): Davies is ANNOUNCED-untrustworthy past I ~ 0.5 mol/kg (the run says so). Pitzer-HMW is built for exactly this regime – valid to I ~ 6 mol/kg for the seawater system, with the E_theta(I) higher-order electrostatic mixing term ACTIVE (Pitzer 1975) – and is CREDENTIALED in this repo by two pinned cases: pitzer_seawater_verify – single-salt oracle 1.57e-14 + HMW seawater mean activity coefficients inside the published bands; pitzer_calcite_brine – SI_calcite / SI_gypsum on surface seawater inside the published oceanographic saturation band. So here we TRUST the Pitzer fork and read Davies as the cautionary curve.

E_theta(I) BEFORE → AFTER (the scan_pitzer fork only; scan_davies is BYTE- IDENTICAL – E_theta is Pitzer-only). At r_max (I ~ 3.3 mol/kg, deep brine where higher-order mixing bites hardest): SI_gypsum_rmax -0.144 → -0.317 SI_calcite_rmax 2.026 → 1.938 SI_gypsum_r0 -0.877 → -0.967 SI_calcite_r0 1.240 → 1.183 I_rmax 3.271 → 3.322 gypsum stays undersaturated end-to-end The engineering verdict (gypsum the limiting scale) is UNCHANGED in direction; E_theta refines the SI magnitude in the high-I tail.



DATA SCOPE: self-DESCRIBING (inline manifest); the ions, pairs, mixing with the carbonate theta/psi/lambda, speciation and minerals resolve from the curated data/standards/ tree at runtime – seal with bin/choupo-import for a runtime-self-contained copy.

precipitation_ro_brackish

tutorials/props/electrolyte/precipitation_ro_brackish

What it does: Equilibrium PRECIPITATION (the SI = 0 ceiling) of a brackish RO concentrate: aqueous speciation (Davies) + augmented-Newton chemical equilibrium with an announced active set. Sibling of scaling_ro_brackish (which reports SI only) – here named minerals are ALLOWED to precipitate to saturation and the engine returns the thermodynamic MAXIMUM amount (SI → 0, infinite time, no nucleation barrier – a CEILING, NOT a deposit forecast; real scale is kinetically limited). Story: (1) pin_gypsum_amount – a CaSO4 water with Ca and SO4 DOUBLED past gypsum saturation; the machine hands back EXACTLY the over-added excess as solid (n_gypsum). (2) feed / feed_eq – the brackish water raw and equilibrated side by side: calcite reaches its ceiling, releases H+ (pH drops, solved closure), and consuming shared Ca pushes gypsum further from saturation. (3) scan_eq – calcite + gypsum allowed across recovery to r = 0.85 with a feedFlow, giving a kg/day calcite curve; gypsum stays n = 0 throughout while its SIeq drifts BELOW the raw free-water SI once calcite consumes the shared Ca – the coupling, visible. Cross-check tool: PHREEQC EQUILIBRIUM_PHASES.

The story: the EQUILIBRIUM-PRECIPITATION ceiling.

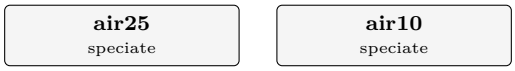
Sibling of scaling_ro_brackish (which is SI-ONLY – "how supersaturated?"). Here the ‘equilibrate { minerals (...); }‘ block names the ALLOWED solids, and the engine drives each to its SI = 0 saturation, returning the amount precipitated. THE FRAMING (printed loudly at run time, non-suppressible):

EQUILIBRIUM CEILING – not a deposit prediction. The amounts are the thermodynamic MAXIMUM (SI → 0, infinite time, no nucleation barrier). Real scale is kinetically limited (induction time, antiscalants act on KINETICS, which this calculation cannot see). Actual deposit <= ceiling, often far less. The safe direction is rigorous: ceiling ~ 0 => no driving force.

ALGORITHM (visible in the trace): augmented Newton in (ln m_j [, ln a_H]) plus one raw-linear n_p per ACTIVE mineral; each master mole balance gains a sink -sum nu_pj n_p; one SI = 0 row per active phase; an OUTER active-set loop ADMITS the most-supersaturated allowed mineral and EVICTS any with n_p < 0, re-solving between, until complementarity holds (SI <= 0 with n = 0, OR SI = 0 with n > 0). A carbonate mineral's H+ leg lands the released H+ in the electroneutrality row (pH solve) – so precipitating calcite ACIDIFIES.

CROSS-CHECK TOOL: PHREEQC EQUILIBRIUM_PHASES (same ceiling framing). Data: curated USGS PHREEQC records (public domain) resolved from data/standards/ at runtime; self-DESCRIBING (inline manifest) – seal with bin/choupo-import for a runtime-self-contained copy.

GOLDEN PINS (locked by the golden master): pin_gypsum_amount Ca = SO4 = 0.030542 mol/kg (DOUBLE the gypsum-saturation value 0.015271) + equilibrate gypsum → SI_gypsum = 0.000 and n_gypsum = 0.015271 (the machine returns EXACTLY the over-added excess). feed_eq calcite + gypsum allowed; calcite reaches SI = 0, releases H+ (pH 7.72 → ~7.50, solved), gypsum stays dissolved. scan_eq r 0 → 0.85 with feedFlow: calcite kg/day ceiling; gypsum n = 0 throughout while SIeq_gypsum drifts BELOW the raw SI_gypsum (calcite eats the shared Ca).



What to expect (golden-locked):

rainwater_air

tutorials/props/electrolyte/rainwater_air

What it does: WATER OPEN TO AIR: the generic multi-gas Henry pin. Pure water equilibrated with the atmosphere (pCO2 4.2e-4, pO2 0.2095, pN2 0.7808 atm) at 25 C and at 10 C. Each listed gas PINS its dissolved species by Henry's law and that master's mole balance is REPLACED by the pin – three pins at once: CO2 chains through the carbonate family (CO2aq is a computed species, the HCO3 row is swapped), while O2 and N2 are inert neutral masters pinned directly. TWO CLASSIC NUMBERS FALL OUT: (1) unpolluted RAINWATER pH ~ 5.6 – carbonic acid from 420 ppm CO2 alone, no pollutant needed; (2) DISSOLVED-OXYGEN saturation ~ 8.5 mg/L at 25 C rising to ~ 11 mg/L at 10 C – gas solubility is RETROGRADE with temperature (K_H analytic from USGS PHREEQC PHASES, public domain), which is why cold streams hold more oxygen than warm ones. The 'totals' entries for HCO3 / O2 / N2 are initial guesses only (announced): in an OPEN system each pinned total is a SOLVED OUTCOME of gas-liquid equilibrium.

The story: water open to AIR: the generic multi-gas Henry pin.

Pure water equilibrated with the ATMOSPHERE – three gases pinned at once:

atmosphere { pCO2 4.2e-4 atm; O2 0.2095 atm; N2 0.7808 atm; }

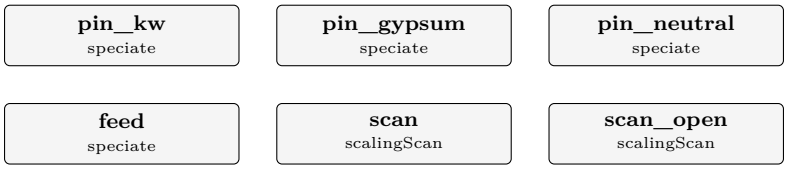
Each gas pins its dissolved species by Henry's law, a = K_H(T) ∗ p, and the pinned master's mole balance is REPLACED by the pin (the OPEN system of SpeciationSolver, generalised beyond CO2). Two pin shapes appear side by side, which is the point of the case:

CO2 dissolves into a COMPUTED species (CO2aq, formed from the HCO3 master): the pin swaps the HCO3 row and the whole carbonate family (CO2aq / HCO3- / CO3–) equilibrates with the gas – DIC is a solved OUTCOME; O2,N2 dissolve into INERT NEUTRAL MASTERS (species/aqueous O2, N2 – identity records, charge 0): the pin replaces each master's own row directly – the dissolved concentration is set by the gas phase alone.

THE TWO CLASSIC NUMBERS (textbook checks, no fitting anywhere):

pH ~ 5.6 unpolluted rainwater: carbonic acid from 420 ppm CO2 only (pH solve; – H+ from electroneutrality against HCO3-); DO 8.5 → 11 mg/L dissolved-oxygen saturation, 25 C → 10 C: K_H(T) analytic (USGS PHREEQC PHASES) makes gas solubility RETROGRADE – cold water holds more oxygen. N2 saturates near 14 mg/L (25 C) for the same reason.

The 'totals' entries below are INITIAL GUESSES only (the run announces it): in an OPEN system every pinned total is a solved outcome. The feed charge-imbalance warning is EXPECTED here – an HCO3 guess with no cation is not a measured analysis; the solved H+ is its physical counter-ion.



Diagnostics locked by the golden master: pH, I, m_CO2aq, and the dissolved O2 / N2 molalities at both temperatures.

What to expect (golden-locked):

scaling_ro_brackish

tutorials/props/electrolyte/scaling_ro_brackish

What it does: RO membrane-scaling audit of a brackish groundwater: aqueous speciation (Davies) with pH SOLVED from electroneutrality (the feed charge imbalance is announced first) + saturation indices SI = log10(IAP/K), scanned over water recovery to r = 0.85 (concentrate = feed/(1-r)) TWICE: closed system (DIC conserved and concentrating) vs open to the atmosphere (a(CO2aq) pinned by Henry at pCO2 = 4.2e-4 atm, DIC a solved outcome – this CO2-rich water degasses, pH and calcite SI jump above the closed curve) – the calcite SI curves differ; that contrast is the lesson. Three analytic pins lock the physics: pure water at given pH 7 reproduces Kw (m_OH ~ 1e-7), a back-computed gypsum-saturated CaSO4 solution gives SI_gypsum ~ 0.00, and pure water with pH solved lands at exactly 7.000.

The story: will my RO concentrate scale?

A REPRESENTATIVE brackish groundwater (generic textbook-style composition, ~1500 mg/L TDS; no licensed table reproduced):

ion mg/L mol/kg w ion mg/L mol/kg w Ca+2 84 0.0021 Cl- 510 0.0144 Mg+2 27 0.0011 SO4-2 250 0.0026 Na+ 363 0.0158 HCO3- 183 0.0030 K+ 12 0.0003 lab pH 7.8 (nominal – see below)

(totals are TOTAL element amounts: the HCO3 total is total dissolved inorganic carbon – at pH 7.8 the reported HCO3 is ~97% of it. Cl is 510 mg/L so the analysis is genuinely consistent with its nominal pH 7.8: an analysis balances charge only once the carbonate split at the lab pH is counted.)

pH IS SOLVED, NOT GIVEN ('pH solve;'): H+ joins the Newton unknowns and ELECTRONEUTRALITY sum z_i m_i = 0 closes the system. Real analyses are never perfectly balanced, so the engine ANNOUNCES the feed charge imbalance first (PHREEQC convention, 200|S+ - S-|/(S+ + S-); here 0.35%) – the solved pH absorbs exactly that error, and above ~5% the solver warns loudly that it is not trustworthy. This feed solves to pH ~7.72, near the lab's nominal 7.8: the analysis is consistent.

UNITS: every 'totals' entry carries its basis (bare numbers are refused). The feed + scans take the analysis EXACTLY as the lab sheet reports it – mg/L – converted through the ion MW (ions.dat) at rho ~ 1 kg/L (dilute aqueous, announced once per run). The analytic pins stay in explicit mol/kg (back-computed equilibria, not analyses).

THE CLOSED-vs-OPEN LESSON (two scans, same feed): scan CLOSED system – every total (DIC included) concentrates as feed/(1-r); the charge-balance ratio is scale-invariant, so the pH only drifts gently (7.72 → 7.58, the Davies gammas at work) while calcite SI climbs 0.23 → 1.38. scan_open OPEN to the atmosphere ('atmosphere { pCO2 4.2e-4 atm; }') – a(CO2aq) is PINNED by Henry, the HCO3 mole balance is REPLACED by the pin, and DIC becomes a solved OUTCOME. This groundwater is ~8x CO2-supersaturated vs the atmosphere, so opening it DEGASES CO2: the pH jumps to 8.54 and climbs to 9.08, and calcite SI lands ABOVE the closed curve (2.59 vs 1.38 at r = 0.85) – why concentrate pH control (acid dosing) matters. Compare the two CSVs (both carry a pH column right after I); the contrast IS the lesson.

VALIDATION PINS (locked by the golden master): pin_kw pure water, pH 7 GIVEN → m_OH = Kw a_w/(a_H gamma_OH) ~ 1.0004e-7 (unchanged) pin_gypsum totals Ca = SO4 = 0.015271 mol/kg, pH 7 GIVEN, BACK-COMPUTED from the catalogue's logK25(gypsum) = -4.55 + CaSO4aq logK25 = 2.14 + Davies at the resulting I = 0.0455 (26% ion pairing) so that SI_gypsum = 0.00 +- 0.001 (unchanged) pin_neutral pure water, pH SOLVED → electroneutrality m_H = m_OH must give pH 7.000 (locks the new charge-balance closure)

Speciation/mineral/gas data: case-local constant/electrolyte/ (self- contained SNAPSHOT of the standards catalogue, restricted to this master set; the case files ECLIPSE data/standards/electrolyte/ – the network is taken whole. Provenance: USGS PHREEQC, public domain – see the .dat headers; the CO2(g) Henry constant is the db's PHASES CO2(g) entry).

softener_brackish

tutorials/props/electrolyte/softener_brackish

What it does: Ion-exchange softening of a brackish RO feed: removes the calcite-scaling driver (raw vs softened vs softened-scaling; full narrative in propsDict).

The story: ion-exchange SOFTENING removes the scaling driver.

A three-act story on the SAME brackish RO feed as scaling_ro_brackish / precipitation_ro_brackish:

(1) raw scalingScan of the raw water: calcite SI > 0 already at the feed and climbing with recovery – the SCALING PROBLEM (a CaCO3-supersaturated concentrate). (2) softened the 'exchange' op equilibrates the SAME water with a strong-acid cation resin (SAC_Na, Gaines-Thomas). Ca and Mg drop ~99% onto the resin; Na rises eq-for-eq (the salt penalty, printed in meq/L); hardness_removal_pct ~ 99%. (3) softened_scaling feed the SOFTENED composition (Ca/Mg gone, Na up) into a scalingScan: SI_calcite is now NEGATIVE across the whole recovery range – the scaling DRIVER is gone. Removing the hardness, not chasing the supersaturation, is the cure.

MODEL (visible in the verbosity>=3 trace): the SAME log-space Newton as speciate, PLUS one master (the free resin site X-), one balance (CEC capacity = sum of equivalents on the sites), and the exchange half-reactions Me(z+) + z X- = MeX (Gaines-Thomas equivalent-fraction activity for the bound species, Davies for the aqueous ions). Divalent Ca2+ (logK 0.8) is equivalent-fraction-favoured and outcompetes Na+; watch the per-iteration selectivity ratio beta(CaX2)/beta(NaX)^2 climb.

CROSS-CHECK TOOL: PHREEQC EXCHANGE (same Gaines-Thomas half-reactions).

THE FRESH-RESIN CAVEAT (printed loudly, non-suppressible): the 'exchange' op returns the LIMITING (fully-equilibrated) effluent – the best a fresh / fully-loaded contactor does per pass. A real fixed bed leaks rising hardness as the exchange front migrates to breakthrough, then must be regenerated; cycle length and breakthrough are TRANSIENT and not modelled here.

Brackish water (I ~ 0.03-0.06): Davies-valid, no Pitzer needed; the honesty banner + the I>0.5 Davies advisory cover the boundary.

Data: curated USGS PHREEQC records (public domain) resolved from data/standards/ at runtime, + the SAC_Na resin nameplate; self-DESCRIBING (inline manifest) – seal with bin/choupo-import for a runtime-self-contained copy.

estimate

The theory you need. When a compound is missing, group contribution builds it: Joback sums first-order group increments into $T_b, T_c, P_c, V_c, \Delta H_f^\circ, \Delta H_{\text{vap}}, c_p^{\text{ig}}(T)$; Lee–Kesler closes ω from (T_b, T_c, P_c); Ambrose–Walton gives $P^{\text{sat}}(T)$ from corresponding states; Rackett the liquid volume. The estimate is a PROPOSAL: a `.dat` you review against any reference data and promote by hand – the engine never estimates at runtime. Molecular structure is IDENTITY: components carry `jobackGroups{}` in their own record, and `bin/estimate <name>` is the one-command curation act. Expect few-percent errors on criticals (and the guide's worked example shows them), weaker T_b for hydrogen-bonded species, and polymers via van Krevelen / Yang on the repeat unit. *Full derivation: Theory Guide, the estimation chapter of the Props Guide.*

estimate_acetone

tutorials/props/estimate/estimate_acetone

What it does: CREATE a component from its groups: Joback estimate of acetone (2 CH3 + 1 ketone), validated against NIST — see the estimate built up from groups

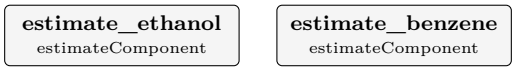
The story: The FIRST stage of the props lifecycle (CREATE → curate → wire → simulate): build a pure-component property set from its molecular GROUPS by Joback group contribution, and SEE each group's contribution add up.

Acetone CH3-CO-CH3 = 2 x CH3 + 1 x ketone (>C=O).

The reference block below validates FOUR numbers – Tb, Tc, Pc, omega – and no others: Joback lands 2.2 % low on Tb, 1.5 % low on Tc, 2.2 % high on Pc (read off the golden against the block, 2026-09-02), and you SEE the error, the whole point of "estimation, then trust". This header used to claim "~2 % on Tc/Pc/Vc and ~0.3 % on dHf"; the block carries no reference Vc and no reference dHf, so those two were claims nothing in the case checks. omega comes from (Tb,Tc,Pc) by Lee-Kesler, not a group sum.

Acetone is 2 × CH3 + 1 × ketone. This case runs under choupoProps and asks Joback's group-contribution method to create a property set from those three groups, then lays the estimate beside the reference values the case itself declares. The golden: Tb 322.11 K, Tc 500.56 K, Pc 48.02 bar, ? 0.30, Vc 209.5 cm^3/mol, ΔHf -217.83 kJ/mol.

1. Estimation is a resolution problem, not a runtime one. Choupo does not estimate properties while a flowsheet runs; it estimates them HERE, at curation time, so a student can look at the number before trusting it. output { proposal auto; } writes the estimate as a record you can read, edit, and only then wire into a case — the run prints where: constant/components/acetone.estimated.dat, with the GAPS the method left listed in its header. 2. The error is the point. Against the reference block in system/propsDict (Tb 329.2 K, Tc 508.1 K, Pc 47.0 bar, ? 0.307): Tb is 2.2 % low, Tc 1.5 % low, Pc 2.2 % high — Joback's usual band for a small ketone, and you can see it rather than be told. 3. ? is not a group sum. It comes from (Tb, Tc, Pc) through Lee-Kesler; an error in Tb propagates into it. That chain is printed in the run's log. 4. A reference is a citation, not an endorsement. The block names where its four numbers were read; the run compares against those four and nothing else.



Open estimate_ethanol_benzene: the same method on a hydrogen-bonding molecule, where Joback's Tb goes noticeably wrong — the honest limit of a group method, shown rather than warned about.

estimate_ethanol_benzene

tutorials/props/estimate/estimate_ethanol_benzene

What it does: Joback estimates: ethanol (H-bonding → Tb weak, the honest limit) and benzene (aromatic groups → good) — see where group contribution wins and loses

The story: Two Joback estimates, side by side, to SEE the method's spread:

ethanol (1 CH3 + 1 CH2 + 1 OH) – a strong H-bonder; Joback's Tb comes out ~14 K LOW (337 vs 351 K). The honest limit, in plain sight. benzene (6 arCH) – aromatic ring; Joback Tc/Tb within ~1.5%. Group contribution at its best.

The lesson is the CONTRAST: an estimate is a starting point whose error you must SEE, not a number to trust blindly.

estimate_petroleum_cut

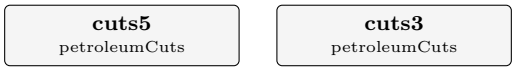
tutorials/props/estimate/estimate_petroleum_cut

What it does: ESTIMATE a petroleum PSEUDO-COMPONENT by name from (Tb, SG) – Riazi-Daubert; see the SCREAMING ESTIMATE provenance and that the lump FLASHES

The story: CREATE a PETROLEUM PSEUDO-COMPONENT from the two bulk measurements every crude assay reports: the normal boiling point Tb and the specific gravity SG. The Riazi-Daubert (1987) correlations turn (Tb, SG) into the corresponding-states constants (MW, Tc, Pc, Vc); omega follows by Lee-Kesler, and the ideal-gas Cp by Kesler-Lee (1976).

This is the SCALAR-input sibling of the Joback group path: a petroleum cut is a LUMP of hundreds of species with NO single molecular structure, so it has NO group decomposition – it is anchored on bulk (Tb, SG), not groups. The estimator is a registered ConstantEstimator (‘model RiaziDaubert;‘), chosen exactly like Joback – the SAME explicit factory.

SEE in the console: the (Tb, SG) anchors and the Watson K factor; the constants built from them, validated against n-decane (a real species at this Tb/SG: Tc ~ exact, omega within ~2 %, Pc/MW within the correlation’s stated ~5-7 %); the proposal .dat whose provenance SCREAMS status ESTIMATE / lumped true / "NOT a real species".



Promote with the printed ‘mv‘, then it FLASHES (see the sibling tutorial steady/flash/flash_pseudoComponent_petCut, which ships this very lump and closes an energy balance with it).

What to expect (golden-locked):

petroleumCuts01_riazi_table36_tbp

tutorials/props/estimate/petroleumCuts01_riazi_table36_tbp

What it does: CUT a TBP curve into petroleum PSEUDO-COMPONENTS (Riazi ASTM MNL50): Tb per cut, SG by constant Watson K, API and Watson K per cut and for the blend, one ESTIMATE record per cut

The story: CUT a TRUE-BOILING-POINT curve into PSEUDO-COMPONENTS. A crude fraction is a continuum of species; a process model needs a handful of lumps. The op 'petroleumCuts' divides the curve into cuts, takes each cut's Tb at the mid-point of its distilled interval, gives it a specific gravity, and hands the pair (Tb, SG) to the SAME Riazi-Daubert estimator 'estimateComponent' uses (MW, Tc, Pc, Vc; omega by Lee-Kesler; Cp by Kesler-Lee). One ESTIMATE record per cut is written into THIS case (constant/components/ petCut_NN.estimated.dat, git-ignored: a proposal you review and promote with 'mv', never a standard record).

THE CURVE AND WHAT IS – AND IS NOT – VALIDATED. The six TBP points are the naphtha-kerosene blend printed in Riazi, "Characterization and Properties of Petroleum Fractions" (ASTM MNL50, 2005), Table 3.6, p. 103 (a TBP column, vol% distilled vs C, quoted there from the API Technical Data Book). The book prints NO cut Tb, cut SG, MW or Tc for it: it uses the curve to illustrate the D86/TBP/EFV interconversions (Example 3.2), and there it estimates the blend's SG as 0.7862 from Eq. 3.17 – the one printed number this case can reproduce, and does (feed SG 0.7862 from 'specificGravityFrom TBP'). EVERYTHING ELSE IS ILLUSTRATIVE: the cut boundaries are this case's choice, and no number is validated against a distillation unit or a measured cut. The ASTM D86 and EFV columns of the same table are NOT used (the op refuses D86 input: the conversion is not implemented).

HOW EACH CUT IS CHARACTERISED (all equations are Riazi's, by number): Tb of a cut = the TBP temperature at the mid-point of its distilled interval (p. 83, footnote a: a mid-point temperature can serve as Tb for a narrow fraction), piecewise-linear between the curve points. SG of a cut = (1.8 Tb)^(1/3) / Kw with ONE Watson factor for the whole feed (Eq. 2.13 rearranged). THIS IS AN ASSUMPTION OF THE OP, NOT A RECOMMENDATION OF THE BOOK; 'method declared;' lets you give the SG of each cut instead. Kw is Eq. 2.13 at the feed SG and the feed's MeABP (Eq. 3.3-3.5), solved by fixed point. API gravity (Eq. 2.4) and Watson K (Eq. 2.13) are published per cut and for the blend. CLOSURE: the cuts re-blended by volume (Eq. 3.45) must reproduce the declared feed SG within the DECLARED tolerance. A miss is announced, never adjusted. Both ops below re-blend about 1 % above the feed SG (the curve is convex and the mid-point Tb is not the cut's mean); op 'cuts5' declares 2 % and closes, op 'cuts3' declares 0.5 % on purpose and prints the announcement. Note that the miss does NOT shrink monotonically with the number of cuts.

SEE: the cut table, the blend line, the closure line, the records.

What to expect (golden-locked):

kind	unit/stream	key	expected

userEstimate01_linear_tb

tutorials/props/estimate/userEstimate01_linear_tb

What it does: User-code property estimation: a student's OWN linear group-contribution Tb estimator (linearTbEstimate), compiled from code/ and linked into choupoProps.

The story: A student's OWN property-estimation op (linearTbEstimate), defined in code/ and linked into choupoProps by bin/buildCode. Tb = base + sum(count∗incr). Here: 198.2 + 2∗23.58 + 1∗76.75 = 322.11 K (the Joback CH3,CH3,ketone sum). —

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	tb_acetone	Tb_K	322.11

vanKrevelen01_polystyrene_density

tutorials/props/estimate/vanKrevelen01_polystyrene_density

What it does: ESTIMATE the density of polystyrene by Van Krevelen group contribution on the repeat unit – glass-box additive sum, Vw from Bondi 1964 (licence-clean via UNIFAC R)

The story: ESTIMATE a POLYMER's repeat-unit DENSITY by group contribution – the polymer sibling of the Joback small-molecule path. Polystyrene's repeat unit -[CH2-CH(C6H5)]- is decomposed into groups; each adds its molar mass and its Bondi van der Waals volume Vw; the sums give

M0 = sum n_i MW_i repeat-unit molar mass Vw = sum n_i Vw_i van der Waals volume (Bondi 1964) V = k ∗ Vw molar volume (k = packing factor) rho = M0 / V density

GLASS-BOX: the console prints every group's contribution – you can redo the whole estimate by hand. M0 is an exact mass-balance fact (104.15 g/mol); rho carries the packing-factor uncertainty (the teaching point below).

LICENCE (the honest part): the Vw group values are Bondi, J. Phys. Chem. 68 (1964) 441 – the PRIMARY per value – derived from the UNIFAC R_k volume parameters Choupo already ships (Vw = R_k x 15.17), NOT copied from the Van Krevelen book table (copyright). See data/standards/parameters/vanKrevelen.dat. Slice 1 ships DENSITY only; Tg / solubility-parameter / Tm are DEFERRED (their open parameters are a separate, correctly-attributed thing).

THE TEACHING POINT – the packing factor k: rho depends on k = V/Vw, the fraction of space the chains do NOT pack into. Default k = 1.60 (amorphous/glassy); crystalline packs denser (~1.43). k is YOURS: change 'polymer { packing k; }' and watch rho move. Atactic PS is amorphous (rho ~ 1.05) – the estimate lands there; a crystalline polymer would need the smaller k. That k is visible (never hidden) is the lesson.

M0 = 104.15 also feeds the step-growth reactor KPIs (Mn = M0/(1-p)) – the same repeat-unit mass, two places.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	vanKrevelen01_polystyrene_density	M0_g_per_mol	104.152
diag	vanKrevelen01_polystyrene_density	V_cm3_per_mol	100.5616
diag	vanKrevelen01_polystyrene_density	Vw_cm3_per_mol	62.851

diag	vanKrevelen01_polystyrene_density	packing_k	1.6

yang2020_Tg_polystyrene

tutorials/props/estimate/yang2020_Tg_polystyrene

What it does: ESTIMATE the glass-transition Tg of polystyrene by the Yang 2020 modified group-contribution scheme (CC-BY) – the repeat unit -CH2-CH(phenyl)- gives Tg(inf)=444 K, an HONEST +19% over-estimate of the measured ~373 K (a teaching point about group-contribution limits)

The story: Yang-2020 Tg estimate + an HONEST limitation

ESTIMATE the GLASS-TRANSITION temperature Tg of polystyrene by the YANG 2020 modified group-contribution scheme. The repeat unit -CH2-CH(phenyl)- decomposes into two Yang main-chain groups:

CH2 : MW 14 Yg 4.026 CHphenyl: MW 90 Yg 42.153

M0 = 14 + 90 = 104 g/mol Yg(inf) = 4.026 + 42.153 = 46.179 (1e3 g.K/mol) Tg(inf) = 46.179∗1e3 / 104 = 444 K

»> THE HONEST TEACHING POINT «< Measured polystyrene Tg ~ 373 K (atactic, high Mw). Yang 2020 gives 444 K – a +19% OVER-ESTIMATE. This is NOT a bug: it is the model telling the truth about itself. The CHphenyl contribution (Yg 42.153) was regressed across the whole training set, and the bulky monosubstituted phenyl pendant is one where an additive main-chain scheme over-predicts the limiting Tg. Box: "all models are wrong, some are useful". The student SEES the deviation (the console prints the per-cent error against the measured anchor) and learns where a group-contribution method earns trust (PVC: 351 vs 354 K, -0.8%) and where it does not (polystyrene: 444 vs 373 K, +19%).

Contrast the flagship ‘yang2020_Tg_pvc‘, where Tg(inf)=351 K reproduces the paper’s Fig 6 value EXACTLY – that case goldens Tg as validated physics. Here Tg is SHOWN (the machinery is identical) but the case exists to expose the over-estimate, so only M0 (an exact mass-balance fact) is goldened, not Tg.

This is Yang 2020 – NOT bare Van Krevelen. Nb (backbone-in-the-side-chain) = 0 for this vinyl polymer.

SOURCE + LICENCE: Yang, Zou, Ye, Zhu, Dong, Bi, ACS Omega 5 (2020) 19655, doi:10.1021/acsomega.0c04499 – CC-BY 4.0; values cited per group as "Yang 2020", never "Van Krevelen".

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	yang2020_Tg_polystyrene	M0_g_per_mol	104
diag	yang2020_Tg_polystyrene	Tg_K	444
diag	yang2020_Tg_polystyrene	YgSum_1e3gKmol	46.18

yang2020_Tg_pvc

tutorials/props/estimate/yang2020_Tg_pvc

What it does: ESTIMATE the glass-transition Tg of poly(vinyl chloride) (PVC) by the Yang 2020 modified group-contribution scheme (CC-BY) – the repeat unit -CH2-CHCl- gives Tg(inf)=351 K, EXACT vs the paper (Fig 6)

The story: FLAGSHIP Yang-2020 glass-transition estimate

ESTIMATE the GLASS-TRANSITION temperature Tg of poly(vinyl chloride) (PVC) by the YANG 2020 modified group-contribution scheme – the polymer sibling of the Joback small-molecule path, for Tg. The repeat unit -CH2-CHCl- is decomposed into two Yang main-chain groups; each adds its limiting Tg contribution Yg(inf):

M0 = sum n_i MW_i repeat-unit molar mass [g/mol] Yg(inf) = sum n_i Yg_i(inf) (+ Nb∗Ygb) limiting Tg function [1e3 g.K/mol] Tg(inf) = Yg(inf) ∗ 1e3 / M0 Tg at infinite Mw [K]

THE ADDITIVE SUM (shown on the console): CH2 : MW 14 Yg 4.026 CHCl: MW 48.5 Yg 17.911

M0 = 14 + 48.5 = 62.5 g/mol Yg(inf) = 4.026 + 17.911 = 21.937 (1e3 g.K/mol) Tg(inf) = 21.937∗1e3 / 62.5 = 351 K <– EXACT vs Yang 2020, Fig 6

This is Yang 2020 – NOT bare Van Krevelen. The scheme predicts the INFINITE- Mw limit Tg(inf); the molecular-weight dependence Tg(Mn) = Tg(inf) - K/Mn is a later slice. Nb (backbone-in-the-side-chain) = 0 for this vinyl polymer, so the bracket is just the sum of the two main-chain group contributions.

SOURCE + LICENCE (the honest part): Yang, Zou, Ye, Zhu, Dong, Bi, ACS Omega 5 (2020) 19655, doi:10.1021/acsomega.0c04499 – CC-BY 4.0, so the parameter values ARE redistributable. Cited per value as "Yang 2020", never "Van Krevelen".

THE GOLDEN: M0 (an exact mass-balance fact) AND Tg(inf)=351 K are checked – Tg here is VALIDATED PHYSICS (it reproduces the paper's Fig 6 value exactly), not just a mass balance. The measured anchor (PVC Tg ~ 354 K) confirms it.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	yang2020_Tg_pvc	M0_g_per_mol	62.5
diag	yang2020_Tg_pvc	Tg_K	351
diag	yang2020_Tg_pvc	YgSum_1e3gKmol	21.937

fit

cp01_polynomial_recovery

tutorials/props/fit/cp01_polynomial_recovery

What it does: Quadratic Cp fit on data generated from a quadratic – exact recovery, with the Kirchhoff Cp_ig - Cp_liq cross-check that ties Cp to dHvap

The story: A LINEAR FIT, AND THE PHYSICS THAT CHECKS IT.

'heatCapacityFit' regresses Cp(T) = A0 + A1 T + A2 T^2 by linear least squares – normal equations, no iteration. Fed data generated FROM a quadratic, it must return that quadratic, so the expected file pins the coefficients rather than a tolerance band.

The interesting number is not the fit. It is KIRCHHOFF:

d(dHvap)/dT = Cp_ig - Cp_liq

The op takes the FITTED liquid Cp and the component's CATALOGUE ideal-gas Cp and reports that difference at the mid temperature. It should be NEGATIVE – the enthalpy of vaporisation falls as T rises, to zero at the critical point – and its size is the slope of dHvap(T). That is the link tying Cp to dHvap to the Antoine fit next door (psat01_antoine_recovery, which reports dHvap from B): three ops, one consistency network, and a student can check one against the other by hand.

Why the case exists: 'heatCapacityFit' had NO case and no gate. Writing the first one for its sibling vaporPressureFit segfaulted choupoProps twice and found a thermoPhysPropDict being silently ignored.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	cp_dce_liquid_fit	A0	194

verdict	cp_dce_liquid_fit	verdict	notClaimed

psat01_antoine_recovery

tutorials/props/fit/psat01_antoine_recovery

What it does: Antoine fit on data generated from Choupo's own water correlation: the coefficients must come back exactly, so any deviation is the op's arithmetic

The story: FITTING ANTOINE, AND KNOWING THE ANSWER BEFOREHAND.

'vaporPressureFit' regresses log10(Psat[bar]) = A - B/(T + C) on measured Psat(T). The fit is linear in (A, B) at fixed C, so the op golden-sections C and solves (A, B) by least squares at each one – derivative-free, and worth reading in the source.

This case feeds it data generated FROM THE SAME EQUATION, by evaluating Choupo's own curated water correlation at twenty temperatures. That is deliberate. Against laboratory data a fit can only be judged to the scatter of the measurements; against data the equation itself produced, the fit must RETURN THE COEFFICIENTS IT WAS GIVEN – so any deviation is the op's arithmetic and nothing else, and the expected file can pin it to the digit.

Why the case exists: 'vaporPressureFit' had NO case and no gate. It could have been broken for a year and the suite would have stayed green; the first to find out would be a student fitting their own data. The psychrometric chart was in exactly that position last week, and writing its first test found it reporting nothing.

What to read in the output: A, B, C – the recovered coefficients, against 5.40221 / 1838.675 / -31.737; R2 – 1 to floating point, because the data has no scatter; dHvap – the Clausius-Clapeyron reading of B WITH the (T/(T+C))^2 correction, at the highest T. Compare it to water's tabulated enthalpy of vaporisation: this is the physical cross-check on a fit that is otherwise just a straight line through transformed numbers.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	psat_water_fit	A	5.40221000142

gibbs

The theory you need. Equilibrium without a mechanism: minimise total Gibbs energy $G = \sum_i n_i \mu_i$ over ALL species subject to elemental balances $\mathbf{A}\,\mathbf{n} = \mathbf{b}$ (Lagrange multipliers per element – printed as λ_E, the element potentials). The species list in the dict IS the model: what you include can form; what you omit cannot. With enough species this reproduces flame temperatures and radical pools with no kinetics at all: expect the adiabatic flame temperature to land within a few K of literature when radicals (H, O, OH…) are IN the pool, and to overshoot by ∼100–250 K when they are not (dissociation is endothermic). Above ∼1500 K the catalogue's polynomial c_p fits extrapolate WRONG – combustion cases carry case-local NASA-9 overrides (NASA/TP-2002-211556), and the case headers say so.

Equilibrium maps. Sweeping the Gibbs solve over a $T \times P$ grid gives an equilibrium map – iso-lines of a product fraction over the operating plane – which shows why an industrial reactor fixes T and P in a narrow window (equilibrium wants one corner, the catalyst works in another; the gap is the compromise). The `temperatureApproach` ΔT – declared as a magnitude; the engine assigns the sign from the reaction's thermicity and announces it – evaluates the *reaction* equilibrium at $T \pm \Delta T$ while enthalpy and the energy balance stay at the physical T – an empirical, calibrated closeness-to-equilibrium knob (never predicted). *Gradeable exercise (ammonia):* on `nh3_equilibrium_map`, at $P = 200$ bar and $\Delta T = 0$, find the temperature at which the equilibrium NH_3 mole fraction crosses 30 %; report T to the grid resolution and verify against the case's anchor KPIs. Unique because the fraction is monotone in T at fixed P. *Full derivation: Theory Guide, the Gibbs-equilibrium chapter, §equilibrium maps.*

landscape01_ammonia_synthesis

tutorials/props/gibbs/landscape01_ammonia_synthesis

What it does: Equilibrium landscape: ammonia synthesis, NH3 mole fraction against T at 1, 10, 100 bar – and the 298 K / 700 K contrast

The story: THE AMMONIA LANDSCAPE – N2 + 3 H2 at stoichiometric feed, equilibrium NH3 mole fraction against temperature at 1, 10 and 100 bar (the ideal-gas element-potential kernel, the same one nh3_equilibrium_map contours over the whole plane). This is the first witness of the EduTool 'equilibrium-landscapes' (gui/src/ui/methods/EquilibriumLandscapesTool.tsx): a SURVEY over reaction systems the engine already solves, read live from this case's 'map.csv' and its anchor KPIs.

WHAT THE THREE CURVES SHOW. Exothermic AND mole-reducing ($4 \rightarrow 2$), so the equilibrium loves COLD and PRESSURE: every curve falls with T, and the 100 bar curve sits above the 1 bar one wherever the gas is dry. The grid starts at 300 K on purpose: from 300 to 380 K the 100 bar cells are a SATURATED gas – the kernel finds NH3 supersaturated there and condenses it (ElementPotential.cpp, the one-condensable two-phase branch), and the mole fraction it reports is the GAS-phase Psat(T)/P. That is why the 100 bar curve RISES with T at its cold end: that leg is ammonia's vapour pressure, not its chemistry, and the curve joins the dry equilibrium at the dew point near 400 K (measured: 0.1047 at 300 K, 0.9311 at 400 K).

THE CONTRAST THE PAGE CLOSES ON, computed here and never typed. Two anchor cells: 298.15 K / 1 bar – ambient, where the reaction is thermodynamically favourable and nothing in this tree can make it go (the only ammonia rate law here, Dyson & Simon 1968, written in the cases that use it, was fitted over 150-300 atm and its effectiveness factor is a table at 150, 225 and 300 atm that the engine REFUSES to extrapolate: tutorials/props/kinetics/ ammoniaRate01_dyson_simon/constant/reactions) – and 700 K / 200 bar, the gibbs10_ammonia_fugacity operating point, which this ideal-gas kernel answers as the SHAPE and that SRK case answers with the fugacity correction folded in. The third anchor, 700 K / 1 bar, is what the same chemistry reaches at converter temperature without the pressure.

Anchor KPI names carry the approach magnitude when one is declared ('metric_T25C_P1atm_dT<n>'), so a changed approach breaks the golden loudly. Nothing here is validated against a measurement: the Larson & Dodge (1923) pins live in nh3_equilibrium_map and are not repeated.

WHY THE PRESSURES ARE 1, 10 AND 100 BAR. 'Pgrid' is 'from / to / n / log' (GibbsMapOp.cpp reads no list form), and three log-spaced points from 1 to 100 bar land on the decades a textbook draws. Ideal-gas validity is the same caveat as nh3_equilibrium_map's: the high-pressure curve is the SHAPE of the pressure dependence, not a quantitative prediction.

temperatureApproach IS DECLARED, AT ZERO. The EduTool's slider replaces the NUMBER of a declared scalar and can add no key (gui/src/case/ methodRun.ts), so the key must be here for the page to move it. Zero is true equilibrium and prints nothing; a magnitude > 0 makes the run assign the sign at EVERY cell from the thermicity of the overall transformation at that cell's T (GibbsMapOp.cpp, 'resolveDirection') and print the tally.

landscape02_water_gas_shift

tutorials/props/gibbs/landscape02_water_gas_shift

What it does: Equilibrium landscape: water-gas shift, CO conversion (carbon in CO2) against T – pressure-indifferent

The story: THE SHIFT LANDSCAPE – equimolar CO + H2O (gibbs01_water_gas_shift's own feed and species set), the fraction of the feed carbon leaving as CO2 against temperature at 1, 10 and 100 bar. 'elementYield' on carbon with CO2 as the product IS the CO conversion here, because every carbon atom fed arrives as CO – and it is the forum-permitted metric (species "conversion" is banned where the species is also produced; docs/design/gibbs-map-forum-2026-07-02.md).

WHAT THE THREE CURVES SHOW, and it is one curve. Exothermic (the conversion falls with T) and mole-CONSERVING ($2 \rightarrow 2$), so the three pressures give the SAME equilibrium to every printed digit: the ideal-gas equilibrium constant of a Delta_n = 0 reaction carries no P. The page draws the three curves on top of each other and says why. MEASURED, not assumed: no cell on this grid condenses – the three pressures agree to every printed digit at all 46 temperatures, which they could not if water had left the gas anywhere (at 400 K the equilibrium leaves 2.5 % water in the gas, 2.5 bar at 100 bar against a 2.46 bar Psat – and the run's own identity of the three columns is the proof, not this estimate).

WHY THE PRESSURES ARE 1, 10 AND 100 BAR. 'Pgrid' is 'from / to / n / log' (GibbsMapOp.cpp reads no list form), and three log-spaced points from 1 to 100 bar land on the decades a textbook draws. Ideal-gas validity is the same caveat as nh3_equilibrium_map's: the high-pressure curve is the SHAPE of the pressure dependence, not a quantitative prediction.

temperatureApproach IS DECLARED, AT ZERO. The EduTool's slider replaces the NUMBER of a declared scalar and can add no key (gui/src/case/ methodRun.ts), so the key must be here for the page to move it. Zero is true equilibrium and prints nothing; a magnitude > 0 makes the run assign the sign at EVERY cell from the thermicity of the overall transformation at that cell's T (GibbsMapOp.cpp, 'resolveDirection') and print the tally.

landscape03_steam_reforming

tutorials/props/gibbs/landscape03_steam_reforming

What it does: Equilibrium landscape: methane steam reforming (S/C 3), carbon left in CH4 against T – pressure hurts

The story: THE REFORMING LANDSCAPE – CH4 + 3 H2O (gibbs02_steam_reforming's own feed and species set), the fraction of the feed carbon STILL in methane against temperature at 1, 10 and 100 bar. Read it as 1 minus the methane conversion: LESS is MORE converted, and the page labels it so rather than subtracting – the metric on the axis is exactly the number the engine wrote. ('elementYield' with CH4 as the "product" is the honest way to ask for the unconverted feed; the metric slot accepts any listed species.)

WHAT THE THREE CURVES SHOW. Endothermic (the slip falls as T rises) and mole-INCREASING (CH4 + H2O → CO + 3 H2, 2 → 4), so pressure HURTS: the 100 bar curve sits far above the 1 bar one, which is why industrial reformers run hot and why the shift on the same catalyst (exothermic, Delta_n = 0) is the one the approach caveat calls GLOBAL – one dT for two reactions of opposite thermicity. The engine reads the OVERALL thermicity from this feed (endothermic at every cell of this grid, the run's own tally) and evaluates the chemistry at T - dT.

WHY THE PRESSURES ARE 1, 10 AND 100 BAR. 'Pgrid' is 'from / to / n / log' (GibbsMapOp.cpp reads no list form), and three log-spaced points from 1 to 100 bar land on the decades a textbook draws. Ideal-gas validity is the same caveat as nh3_equilibrium_map's: the high-pressure curve is the SHAPE of the pressure dependence, not a quantitative prediction.

temperatureApproach IS DECLARED, AT ZERO. The EduTool's slider replaces the NUMBER of a declared scalar and can add no key (gui/src/case/ methodRun.ts), so the key must be here for the page to move it. Zero is true equilibrium and prints nothing; a magnitude > 0 makes the run assign the sign at EVERY cell from the thermicity of the overall transformation at that cell's T (GibbsMapOp.cpp, 'resolveDirection') and print the tally.

landscape04_methane_combustion

tutorials/props/gibbs/landscape04_methane_combustion

What it does: Equilibrium landscape: methane combustion in stoichiometric air, carbon in CO2 against T – complete until dissociation

The story: THE COMBUSTION LANDSCAPE – CH4 in stoichiometric air (gibbs03's own feed and species set), the fraction of the feed carbon fully oxidised to CO2 against temperature at 1, 10 and 100 bar, 600 to 2500 K.

WHAT THE THREE CURVES SHOW, and it is where the approach is INDIFFERENT. Below about 1500 K the equilibrium is complete conversion to better than 0.2 % (0.99996 at 600 K, 0.9987 at 1500 K and 1 bar) – a flat line at 1 on any axis a plot can draw – and a 50 K approach moves it by nothing visible: the whole conversion-versus-temperature curve is flat, so a HORIZONTAL shift along it changes nothing. Only above ~1800 K, where CO2 starts to dissociate to CO, does the curve acquire a slope and the approach a visible effect, and pressure holds the CO2 together (the dissociation makes moles). This is the page's counterexample to the ammonia and reforming systems, where the same 50 K moves the answer by a great deal.

The grid starts at 600 K rather than 300 K by measurement: on a 300 K start the cells at 300 and 350 K (every pressure), 400 K / 10 bar and 500 K / 100 bar did NOT converge – the product water is far below its dew point there and the gas-only Newton the kernel runs first does not reach a root – and a witness that ships hatched cells at its cold end teaches nothing the 600 K plateau does not. From 600 K up every cell converges dry (y_H2O P stays below Psat on the whole grid).

WHY THE PRESSURES ARE 1, 10 AND 100 BAR. 'Pgrid' is 'from / to / n / log' (GibbsMapOp.cpp reads no list form), and three log-spaced points from 1 to 100 bar land on the decades a textbook draws. Ideal-gas validity is the same caveat as nh3_equilibrium_map's: the high-pressure curve is the SHAPE of the pressure dependence, not a quantitative prediction.

temperatureApproach IS DECLARED, AT ZERO. The EduTool's slider replaces the NUMBER of a declared scalar and can add no key (gui/src/case/ methodRun.ts), so the key must be here for the page to move it. Zero is true equilibrium and prints nothing; a magnitude > 0 makes the run assign the sign at EVERY cell from the thermicity of the overall transformation at that cell's T (GibbsMapOp.cpp, 'resolveDirection') and print the tally.

landscape05_thermal_no

tutorials/props/gibbs/landscape05_thermal_no

What it does: Equilibrium landscape: thermal NO in methane-air combustion products against T – the GLOBAL caveat, drawn

The story: THE THERMAL-NO LANDSCAPE – CH4 in stoichiometric air with NO in the species list (gibbs06_thermal_nox's own feed and species set), the equilibrium NO mole fraction against temperature at 1, 10 and 100 bar, 1000 to 2500 K. The page draws it on a LOG axis: it spans many decades (read the two ends off the CSV rather than off this sentence).

WHAT IT IS HERE FOR, and it is the sharpest thing on the page. NO formation (N2 + O2 → 2 NO) is ENDOTHERMIC – the curve RISES with T – but it rides inside a feed whose OVERALL transformation, methane burning, is exothermic. The engine reads the direction from the overall thermicity of THIS feed at each cell (GibbsReactor::approachDirection, the one home; GibbsMapOp calls it per cell), finds every cell exothermic, and evaluates the chemistry at T + dT. For the combustion that is the conservative direction. For the NO riding inside it, T + dT sits HIGHER on a rising curve: the declared approach reports MORE NO than the equilibrium at the physical T – an outlet beyond equilibrium for the minor product. That is the engine's own GLOBAL caveat ("it cannot resolve per-reaction approaches") drawn as a curve rather than printed as a sentence, and the page says it is a limitation of the single-number model, not a finding about flames.

Pressure: 2 → 2 for NO formation, so the 1 and 10 bar curves nearly coincide; the small spread that remains comes from the combustion products' own dissociation equilibria, which do carry P.

WHY THE PRESSURES ARE 1, 10 AND 100 BAR. 'Pgrid' is 'from / to / n / log' (GibbsMapOp.cpp reads no list form), and three log-spaced points from 1 to 100 bar land on the decades a textbook draws. Ideal-gas validity is the same caveat as nh3_equilibrium_map's: the high-pressure curve is the SHAPE of the pressure dependence, not a quantitative prediction.

temperatureApproach IS DECLARED, AT ZERO. The EduTool's slider replaces the NUMBER of a declared scalar and can add no key (gui/src/case/ methodRun.ts), so the key must be here for the page to move it. Zero is true equilibrium and prints nothing; a magnitude > 0 makes the run assign the sign at EVERY cell from the thermicity of the overall transformation at that cell's T (GibbsMapOp.cpp, 'resolveDirection') and print the tally.

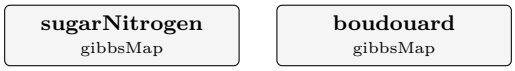
landscape06_nitrogen_fixation_routes

tutorials/props/gibbs/landscape06_nitrogen_fixation_routes

What it does: Nitrogen fixation, three overall routes on one formation surface: heterotrophic (sugar as the electron donor), phototrophic (water), and Haber-Bosch – dG as the engine prices it

The story: THREE OVERALL ROUTES TO FIXED NITROGEN, PRICED ON ONE SURFACE. The sixth witness of the EduTool ‘equilibrium-landscapes‘ (gui/src/ui/methods/EquilibriumLandscapesTool.tsx) and the first case of the ‘reactionGibbs‘ property operation (src/propertyOps/ReactionGibbs.cpp), which exists because of it.

WHY A NEW OP WAS NEEDED, measured before it was written. The engine’s one route to a reaction’s Gibbs energy, ‘Reaction::equilibrium‘ (src/thermo/reaction/Reaction.cpp), prices every species on the ideal-gas rung with ‘g_pure_ig(T)‘, and that rung REFUSES a record tabulated on the solid standard state. A gibbsMap with glucose beside the gases was run and refused, verbatim: "Component ’glucose’: h_pure_ig(T) evaluates the IDEAL-GAS rung, but this record declares standardThermochemistry. referenceState pureSolid – dHf_298 and s_298 are tabulated on the solid standard state, so reading them here would be wrong by a heat of sublimation." The same refusal binds ‘equilibriumReactor‘ and ‘gibbsReactor‘. The biological routes are exactly a solid sugar and liquid water beside gases, so no reactor and no existing op could price them; ‘reactionGibbs‘ sums a DECLARED reaction over the phase-aware ‘h_formation‘ / ‘s_formation‘ surface the Component already carried.



THE THREE ROUTES (constant/reactions), balanced by ELECTRON COUNT – the biological ones carry NO H2 (Vitor’s correction, 2026-09-27: nitrogenase reduces N2 with protons and electrons that come from the organism’s substrate): heterotrophic C6H12O6(s) + 4 N2 + 6 H2O(l) → 6 CO2 + 8 NH3 phototrophic N2 + 3 H2O(l) → 2 NH3 + 3/2 O2 haberBosch N2 + 3 H2 → 2 NH3 Every species is priced on a DECLARED standard state (‘phases {}‘): the sugar on its own pureSolid rung, water as a pure liquid reached by the vaporisation crossing from its ideal-gas datum (announced), the gases on idealGas. The lesson’s expectation, stated before the run: the sugar route is EXERGONIC (respiration pays for fixation), the water route is ENDERGONIC (light pays), the industrial route is exergonic at 298 K and loses that with temperature – the landscape witness beside this case draws the loss.

TWO TEMPERATURES, AND WHY ONLY THE FIRST IS ASKED OF THE SUGAR ROUTE. 298.15 K is the datum temperature, where a declared rung answers with no heat capacity integrated. glucose.dat carries NO heat-capacity block on any rung ("FLAGGED, NOT FABRICATED", its own words), so asking the heterotrophic route at 310.15 K REFUSES by name – measured, verbatim: "Component ’glucose’: h_formation liquid leg needs liquidHeatCapacity" (the solid leg falls back to the liquid Cp and finds none). The refusal is the finding and is quoted on the page; this case therefore prices all three routes at 298.15 K in one op and the two routes that can move in temperature at 310.15 K in a second op, so that the run passes and the gap is stated rather than papered over; a third op prices the industrial route alone at 700 K, the converter temperature of gibbs10, where its dG has changed sign – which is the whole reason the converter needs its pressure, and the landscape witness beside this case draws it. Liquid water is not asked at 700 K: a pure-liquid standard state above the critical temperature is a number with no state behind it.

NOTHING HERE IS A RATE. An exergonic route is one the equilibrium permits; what makes each one go – the enzyme’s ATP, the light, the iron catalyst’s temperature – is outside every record in this tree, and the ATP stoichiometry of nitrogenase is deliberately NOT cited because no reference for it exists in the repository.

landscape07_sugar_nitrogen_all_pathways

tutorials/props/gibbs/landscape07_sugar_nitrogen_all_pathways

What it does: Gibbs maps with a pure solid: the sucrose nitrogen-fixation reactants with every pathway open, and Boudouard carbon

The story: TWO GIBBS MAPS THAT CARRY A PURE SOLID, the first cases to (2026-09-29). Until that day ‘gibbsMap‘ called the fluid-only solve, so a species whose record declares ‘referenceState pureSolid;‘ was priced on the ideal-gas rung and its record refused the whole map (found by Vitor, mapping sucrose beside the gases). The op now calls ‘GibbsMethod::solve‘, the one home the gibbsReactor already used: a declared pure solid is its own phase at activity one, deposited only where the solid-free equilibrium would supersaturate it, and its amount is the CSV column ‘s_<name>‘.

sugarNitrogen – the REACTANTS of the sucrose nitrogen-fixation route C12H22O11(s) + 8 N2 + 13 H2O → 12 CO2 + 16 NH3 (balanced by electron count; its dG at 298.15 K, 1 bar is about -355 kJ per sucrose on ‘reactionGibbs‘, so the ROUTE is permitted), handed to a Gibbs map with every species open, methane included. Where the atoms go at minimum G is NOT that route: measured, the carbon ends as methane and CO2 (the anaerobic digester’s answer), the nitrogen stays N2 and ammonia is near 1e-6 at ambient. A declared route that is permitted is not the route equilibrium picks; the organism picks it with an enzyme.

boudouard – 2 CO <→ C(graphite) + CO2, CO fed alone: carbon DEPOSITS at low temperature and not at high, pinned as the fraction of the fed carbon that leaves as graphite (elementYield on the solid).

NOT HERE, said: a solid that must REMAIN for the atoms to close. With the six species sucrose, CO2, N2, NH3, H2, water and no methane, carbon has one fluid carrier (CO2) and too little oxygen for it, so the solid-free equilibrium the solid test starts from does not exist; every cell reports unconverged, with the solver’s own cause printed. That is a limit of GibbsMethod::solve, the same in the gibbsReactor, recorded in DEV.md section 5, not fixed here.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	sugarNitrogen	metric_T25C_P1atm	1.27109422855e-06
diag	sugarNitrogen	metric_T37C_P1atm	2.67461125111e-06

diag	boudouard	n_cells	30
diag	boudouard	n_unconverged	0

nh3_equilibrium_map

tutorials/props/gibbs/nh3_equilibrium_map

What it does: Ammonia equilibrium map (T x P): why Haber runs at 400-500 C and 150-300 bar

The story: THE HABER MAP – the forum-ratified Gibbs equilibrium map (docs/design/gibbs-map-forum-2026-07-02.md) on its canonical pilot: N2 + 3 H2 at stoichiometric feed, equilibrium NH3 mole fraction contoured over 300-700 C x 1-300 bar. The map shows the whole Haber story at a glance: equilibrium loves COLD and PRESSURE (exothermic, Delta_n < 0); the industrial window (400-500 C, 150-300 bar) sits where the catalyst can actually work – the tension IS the lesson.

VALIDATION ANCHORS (golden-locked; verified 2026-07-03): the classic measurements of Larson & Dodge, J. Am. Chem. Soc. 45 (1923) 2918 – 400 C / 10 atm: engine 4.09 % vs L&D 3.85 % (+6 %) 450 C / 10 atm: engine 2.22 % vs L&D 2.11 % (+5 %) The ~5 % offset is consistent with propagating the JANAF formation-data uncertainty of NH3 into Kp (exp(-dG/RT) amplifies ~0.2 kJ/mol into ~5 %) – honest agreement for an equilibrium constant spanning decades. IDEAL-GAS VALIDITY: the kernel is ideal-gas, so pins stay at <= 50 atm, 350-500 C (the forum's chair: at 300 bar a temperatureApproach would silently absorb the missing fugacity corrections – announced, and the high-P corner of this map is drawn as EQUILIBRIUM SHAPE, not quantitative prediction).

temperatureApproach: 0 here (true equilibrium). Re-run with e.g. 'temperatureApproach 25;' to see the contours slide – the empirical closeness-to-equilibrium parameter industry quotes in C (announced loud, the anchor KPI names then carry _dT25 so the golden breaks visibly).

What to expect (golden-locked):

kind	unit/stream	key	expected

diag	haber_map	n_unconverged	0

reactionEnthalpy01_haber_kirchhoff

tutorials/props/gibbs/reactionEnthalpy01_haber_kirchhoff

What it does: The reaction enthalpy is a function of temperature: N2 + 3 H2 → 2 NH3 priced from 25 C to 527 C on the formation surface – the witness of the reaction-enthalpy EduTool

The story: THE REACTION ENTHALPY IS A FUNCTION OF TEMPERATURE. The ammonia synthesis N2 + 3 H2 → 2 NH3, every species an ideal gas at the standard pressure, priced by 'reactionGibbs' at seven temperatures from 298.15 K (where formation enthalpies are tabulated) to 800 K (above an ammonia converter):

dH°(T) = sum_i nu_i h_i(T), h_i(T) = dHf_i(298.15 K) + int Cp_i dT

The "°" fixes the standard state (1 bar, ideal gas); it does not fix the temperature. At 298.15 K the result is -91.88 kJ per mole of reaction, i.e. -45.94 kJ per mole of NH3; at a converter's 700-800 K it is about -53 kJ per mole of NH3 – the 25 C value under-states the heat a converter releases by about 14 %. The witness of the EduTool 'reaction-enthalpy' (DEV.md 4c, C31). The constant/ tree is landscape06's, copied whole: the same formation surface, so the 298.15 K and 700 K rows reproduce that case's own 'routes298' and 'haber700' Haber-Bosch rows.

The witness of the EduTool Reaction enthalpy and temperature (reaction-enthalpy). One reactionGibbs operation prices N_2 + 3 H_2 → 2 NH_3 (ideal gases at 1 bar) at seven temperatures, from 298.15 K to 800 K, on the formation surface of the catalogue records.

The degree sign fixes the standard state (1 bar, each species in its reference phase), not the temperature: tables are printed at 298.15 K by convention. A converter running at 700–800 K releases about 16 % more heat per mole of ammonia than the 25 °C value says.

constant/ is copied whole from [landscape06_nitrogen_fixation_routes](../landscape06_nitrogen_fixation_routes), so the formation surface is the same one; this case reads only N_2, H_2 and NH_3.

What to expect (golden-locked):

... and 14 more reference values in the case's `expected`.			

heat

The theory you need. Heat exchange couples streams without mixing them: $Q = U\,A\,\Delta T_{\mathrm{lm}}$, effectiveness-NTU when outlets are unknown. Utilities (steam levels, cooling water) are allocated by temperature level – a reboiler cannot be heated by a colder utility, and the allocator says which level it picked. Heat-links (forward and feedback) couple distant units into an energy tear the solver converges like any recycle. Pinch analysis finds the minimum utilities the composite curves allow.

Exchanger DESIGN vs rating. A shell-and-tube poses two inverse questions: RATE it (geometry given → find U, area, ΔP, duty – `model geometry;`) or DESIGN it (duty given → size the geometry – `model design;`). U is BUILT from the two film coefficients (Gnielinski tube, Kern shell) and the wall; the pressure drop (Kern both sides) is the duty-vs-pumping half a real design lives by. The standard workflow – establish the duty, THEN design, THEN rate, never invent the geometry up front – is walked end-to-end in the two-part sequence `hxWorkflow1_design_from_duty` → `hxWorkflow2_rate_designed`, and the design ends in a printable datasheet (GUI: the unit panel). *Full derivation: Theory Guide, the heat-integration chapter, §heat-exchanger design.*

bellDelaware01_hewitt_example62

tutorials/props/heat/bellDelaware01_hewitt_example62

book	exact
bellDelawareBench	bellDelawareBench

What it does: Bell-Delaware shell side – Hewitt, Shires & Bott Example 6.2 reproduced step by step at the book's own declared fluid and geometry (J_L, J_B, R_L, R_B read from Bell's charts and declared, as the textbook does; 'auto' computes them instead).

The story: the Bell-Delaware shell-side rating on the textbook's own worked example.

SOURCE. G. F. Hewitt, G. L. Shires, T. R. Bott, ∗Process Heat Transfer∗ (CRC Press, 1994), Example 6.1 (the geometry and the light-hydrocarbon stream) and Example 6.2 (the Bell-Delaware solution, pp. 280-285), with the method of Section 6.3.2 (Eqs 6.8-6.19, 6.20, 6.22, 6.26-6.31) and the ideal bank of Eq 2.218 / Table 2.5.

WHAT IS DECLARED, AS THE BOOK DOES. Bell's J_L, J_B (Figs 6.8, 6.9) and R_L, R_B (Figs 6.10, 6.11) are CHART READINGS in this method; the book reads J_L = 0.58, J_B = 0.92, R_L = 0.33, R_B = 0.76 and so does this case. Each factor is a declared number (the chart reading) or the word 'auto' (Taborek's closed form, HEDH 3.3; the gate runs this geometry with 'auto' and holds the four values to the book's readings within the reading error); an absent one refuses by name. The fluid properties are the book's too (the bench is the textbook's inputs, not a package's), which is why this is a props bench.

WHAT THE BOOK PRINTS, AND WHAT THIS RUN GIVES (the gate holds every row): S_m 0.01667 m2 (book) 0.016622 from Eq 6.9 as written: the book's S_m is 0.3 % high. Op 'book' starts from the PRINTED S_m and reproduces every digit; op 'exact' starts from the geometry Re 2.097e4 Pr 7.481 ideal h 1418 W/m2K F_c 0.6470 J_c 1.016 (S_sb+S_tb)/S_m 0.4187 F_bp 0.2666 h 769 W/m2K K_f 0.3657 N_c 8.5 dp_c 233 Pa dp_w 165 Pa shell dP 4501 Pa

bellDelaware02_serth_example61

tutorials/props/heat/bellDelaware02_serth_example61

chart	equations
bellDelawareBench	bellDelawareBench

What it does: Bell-Delaware shell side, form Serth – Serth Example 6.1 with every correction factor computed (J_L, J_B, R_L, R_B auto) and the ideal bank read from Fig 6.1 (op chart) or from Eqs 6.1-6.4 (op equations).

The story: the Bell-Delaware shell side, FORM SERTH, on the textbook's own worked example.

SOURCE. R. W. Serth, ∗Process Heat Transfer: Principles, Applications and Rules of Thumb∗ (Academic Press / Elsevier, 2007), Example 6.1 (the final kerosene/crude-oil exchanger of Example 5.1, 124 tubes of 1.0 in OD on a 1.25 in square pitch in a 19.25 in shell), with Sections 6.4-6.7 (Eqs 6.6-6.57) and Table 6.1. Inputs below are the book's, converted to SI (1 in = 0.0254 m exactly; 1 lb = 0.45359237 kg; 1 Btu/lb F = 4186.8 J/kg K).

UNLIKE HEWITT'S EXAMPLE, every correction factor here is COMPUTED ('auto'): J_L, J_B, R_L, R_B from Eqs 6.48-6.53, J_S = R_S = 1 (equal spacing, Eqs 6.54-6.55) and J_R = 1 (Re > 100, Eq 6.57). Op 'chart' declares the ideal bank as the book's example reads it from Fig 6.1 (j = 0.0060, f = 0.09); op 'equations' computes j and f from Eqs 6.1-6.4 (the book prints 0.0063 and 0.089 for them).

CLEARANCES. Serth's Eqs 6.22 and 6.36 use d_tb and d_sb as the gap itself and his Example 6.1 inserts the TEMA values (0.4 mm; 0.8 + 0.002 D_s mm plus a 0.75 mm allowance) in them, so 'clearanceBasis radial;' is the reading that reproduces his printed S_tb, S_sb, J_L and R_L; 'diametral' would halve both areas and the gate shows it does NOT reproduce them.

PRESSURE DROP. The printed summary Eq 6.16 omits R_L on the central spaces while Eq 6.9 has it; the example's own arithmetic (dP_f = 159.4 lbf/ft2) needs it, so Eq 6.9 is used and Eq 6.16 is a candidate erratum.

htbench01_correlations

tutorials/props/heat/htbench01_correlations

What it does: Heat-transfer correlation bench – each convective correlation (Dittus-Boelter, Gnielinski, Kern) verified against its published Nusselt anchor. Dittus-Boelter and Gnielinski are pinned to Incropera & DeWitt 6th ed. Example 8.4; Kern's closed j_H form is self-consistency-checked (its original pin is a chart). AAD tolerance 5% honours textbook rounding + the correlations' own scatter.

The story: the heat-transfer correlation self-check bench.

Mirrors the membrane mass-transfer story (Sherwood) on the heat side (Nusselt): each registered convective correlation RUNS its verify() against a published Nu anchor and the deviation is printed + locked.

DittusBoelter Nu = 0.023 Re^0.8 Pr^0.4 (Incropera Ex 8.4, Nu=205) Gnielinski Nu = (f/8)(Re-1000)Pr/[..] (Incropera Ex 8.4 alt, Nu=224) Kern (shell) Nu = 0.36 Re_s^0.55 Pr^1/3 (Kern PHT; closed-form check)

The per-correlation deviation diags are the golden KPIs.

psychro01_n2_water

tutorials/props/heat/psychro01_n2_water

What it does: Psychrometric chart for N2/water at 1 atm, 0-60 C: saturation + four RH lines + three adiabatic-saturation lines, from the vapour-pressure model a flash would use

The story: THE PSYCHROMETRIC CHART, computed rather than looked up.

Nitrogen + water at 1 atm, 0 → 60 C: the saturation curve, four relative-humidity lines and three adiabatic-saturation (wet-bulb) lines, all from the SAME vapour-pressure model a flash would use. Nothing here is a chart digitised from a handbook – the curve is Y_sat(T) evaluated point by point, so the student can change the model and watch the chart move.

Why this case exists at all: 'psychrometricChart' is reachable from the GUI's Property Explorer, and until now NOTHING exercised it. It could break and the whole suite would stay green; the first to find out would be a student opening the Explorer. An op a user can reach and a test cannot is a promise with no guard behind it.

What to read in the output (long-format CSV: T_C, Y, curve): 'saturation' – Y_sat = 0.622 ∗ Psat/(P - Psat), the chart's ceiling; 'RH=...' – the same expression at a fraction of Psat, so the lines fan out and steepen with T exactly as the printed chart does; 'wetBulb=...' – the adiabatic-saturation lines, which are NOT parallel to the RH lines: they carry the latent heat of the water evaporated, so their slope is set by Hvap/cp of the moist air, not by geometry.

What to expect (golden-locked):

psychro02_air_water

tutorials/props/heat/psychro02_air_water

What it does: Psychrometric chart with dry AIR as the carrier (the textbook object): saturation, RH, adiabatic-saturation and true wet-bulb families at 101.325 kPa, Lewis ~ 0.851 – the case-local air component deliberately shadows the catalogue mixture alias

The story: THE TEXTBOOK CHART: dry AIR as the carrier, not a stand-in. Twin of psychro01_n2_water with the REAL carrier – the lumped pseudo-component air (MW 28.96, ChemSep v8.3), which this case declares CASE-LOCALLY in constant/components/air.dat. That declaration is load-bearing, not a convenience: the catalogue also holds mixtures/air.dat (an expansion table, air → N2 + O2 + Ar), and the settled precedence – the case always overrides – is what makes the token load as the COMPONENT here; the run announces the shadowed expansion. Until 2026-08-31 that tie went to the mixture unconditionally and this exact case refused with "carrier 'air' is not a component".

What the twin buys over psychro01: Y_sat(60 C) = 0.1534 against the ~0.152 a printed air chart reads (N2 gives 0.1586 – the 3.4 % MW error the registry note predicted), and Lewis = 0.851, the handbook air/water value the Le^(2/3) wet-bulb family exists to teach.

hydraulics

The theory you need. Pressure drop and flow distribution: Darcy–Weisbach with friction factors, fittings as equivalent lengths, pump curves against system curves. Expect the operating point at the curves' intersection.

letdown02_valve_fluid_properties

tutorials/props/hydraulics/letdown02_valve_fluid_properties

What it does: The two valve inlets of letdown01: the loop purge's Cp/Cv and Z at 140 bar (is the gas letdown choked?) and liquid ammonia's vapour pressure at 253 K (does the liquid letdown cavitate or flash?)

The story: THE TWO FLUID PROPERTIES A LETDOWN VALVE IS JUDGED BY (DEV.md 4c C64, the "Large pressure letdown" EduTool).

The throttles themselves run in tutorials/steady/hydraulics/ letdown01_ammonia_flashing. A valve's hydraulic regime is decided by two more numbers, which a flowsheet unit does not publish, so this props case computes them at the two valve inlets of that case:

the GAS: the loop purge at 140 bar and 253.15 K, let down to a fuel header. Whether its flow is choked is decided by the ratio of specific heats k = Cp/Cv – propertyPoint's 'gamma', Cp_ig/(Cp_ig - R), the ideal-gas ratio the critical-pressure-ratio formula is derived with – and the SRK compressibility Z. the LIQUID: the 20 bar drum liquid of letdown01, at the temperature its first throttle left it (253.01420618 K, copied from that case's converged/LetdownLiquid; gui/tests/letdown.test.ts holds it to the ValveHP T_out golden). Whether its second throttle cavitates or flashes is judged by the ammonia's VAPOUR PRESSURE at that temperature, Psat_NH3 (the record's Antoine curve), against the pressure at the valve's vena contracta – the PURE ammonia's, so for a liquid holding dissolved gas a didactic approximation.

Compositions are the component flows in kmol/h exactly as letdown01's converged streams print them; propertyPoint normalises them. The liquid's dissolved H2, N2 and Ar do not enter Psat_NH3 – that key is the pure ammonia's vapour pressure, the P_v of the valve-sizing equations. The drum liquid is in equilibrium with its gas at 20 bar, so even a small drop below it can begin to release the gas it still holds, and that is letdown01's to show, not this case's.

moody01_friction_correlations

tutorials/props/hydraulics/moody01_friction_correlations

What it does: The Moody chart's four correlations, each verified against its own published anchor and then all asked the same question – so the disagreement is visible instead of hidden behind a default

The story: moody01 – FOUR CORRELATIONS, ONE QUESTION, FOUR ANSWERS.

The Darcy friction factor is the most-used correlated quantity in chemical engineering, and every simulator computes it. What none of them shows is that the answer DEPENDS ON WHICH CORRELATION YOU PICKED.

Choupo has computed Blasius, Colebrook-White, Haaland and Churchill since the pipe unit was written – correctly, with their citations in comments, as free functions nobody could name or reach. This case is what happens when they become objects: each states the window its own authors gave it, each carries its primary citation, each reproduces a published anchor on every run, and all four can be asked the same question at once.

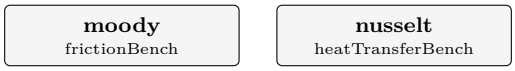
WHAT THE RUN DOES, IN TWO PARTS.

(1) VERIFY. Each correlation reproduces its own anchor, and the anchors are deliberately of DIFFERENT KINDS, because what can be checked differs:

Blasius against its own closed form. This checks the ARITHMETIC and nothing else, and the bench says so rather than letting a 0.000 % deviation look like a validation. Colebrook against the fully-rough von Karman limit, where the implicit equation has a closed form. This checks that the FIXED-POINT ITERATION reaches the answer it must. Haaland against COLEBROOK at the same point – because Haaland's own published claim is "I reproduce that equation within about 2 %". Anchoring it to anything else would be checking a claim nobody made. Churchill against the EXACT laminar law f = 64/Re, which its single expression contains as its own low-Re limit. This is the strongest of the four: a mis-typed exponent fails here while the turbulent branch still looks plausible.

(2) COMPARE. All four are evaluated at Re = 1e5, eps/D = 1e-3 – an ordinary turbulent water line in a commercial steel pipe – and the spread is published as a number.

WHAT TO READ IN THE OUTPUT. Blasius is the one to watch: it carries NO roughness term at all, so at eps/D = 1e-3 it answers as though the wall were smooth, and it is simply wrong. It says so on its own line. That is the whole lesson of a validity window – not that the correlation is bad, but that it was asked a question it was never fitted for, and only the window can tell you.



WHAT THIS CASE DOES NOT DO. It does not say which correlation is right. That depends on the pipe – its roughness, whether the flow is developed, whether the duct is even circular – and a bench that ranked them would hide the choice the engineer has to make, which is exactly what a default does today in every tool that has one.

moody02_correlation_sweeps

tutorials/props/hydraulics/moody02_correlation_sweeps

What it does: The friction-factor and Nusselt correlations swept across five decades of Reynolds number – the engine's own curves, which the EduTool on why correlations are simple draws, differentiates and fits

The story: moody02 – THE CORRELATIONS AS CURVES, NOT AS POINTS (DEV.md 4c C119).

moody01 asks four friction correlations ONE question and publishes their disagreement. This case asks them the same question at every Reynolds number from 1e2 to 1e8, and asks the Nusselt correlations the same at every Reynolds number from 2e3 to 2e7, and writes the answers as two CSV files. It is the witness of the EduTool "Why engineering correlations are simple", which draws, differentiates and fits these curves in the browser – so every curve on that page is the engine's own correlation, the one the pipe and the heat exchanger use, never a re-typed copy.

WHAT IS SYNTHETIC, said plainly. The CSVs hold no measurement. They are the correlations evaluated on a grid, and the EduTool treats them as the "truth" a student fits a power law to – which is the exercise, because the point it teaches is how simple a curve looks over a narrow range, not how well any correlation matches a laboratory.

WHAT THE TWO SWEEPS WRITE.

moodySweep.csv one row per (eps/D, Re): every friction correlation's f and its own window flag (1 inside, 0 outside), the regime the engine names (laminar below 2300, transition to 4000, turbulent above), and Churchill's two asymptotes fL = 64/Re and fT – the pieces its single expression blends as (fL^12 + fT^12)^(1/12).

nusseltSweep.csv one row per (Pr, Re): every single-phase Nusselt correlation's Nu and window flag. Each correlation is handed a unit fluid whose Re and Pr ARE the grid point; heating side. Kern is SHELL-side and is evaluated on the same numbers – it is not a tube correlation.

The grid is logarithmic, 20 points per decade, so every decade holds 21 points, its two ends included – the EduTool's one-decade power-law fit uses exactly those. The Nusselt grid starts at 2e3 because Gnielinski's expression carries (Re - 1000) and is zero at Re = 1000.

kinetics

ammoniaRate01_dyson_simon

tutorials/props/kinetics/ammoniaRate01_dyson_simon

What it does: The ammonia synthesis rate of Dyson & Simon (1968), WRITTEN in the case (constant/reactions, 'type expression', every constant with its unit and equation number) and put on the rate-law bench: Eq 19's pseudo-homogeneous rate, Eq 39's effectiveness factor as a declared table over Table I's three pressures, Eq 40, a declared 150-300 atm window and an announced pressure interpolation; the paper's anchors are held by a gate on every case's copy of the law. It locates the LOCUS OF MAXIMUM RATE at three conversions and shows it descending – the curve ammonia03_quench_converter zigzags about – and evaluates the rate at that converter's own bed states.

The story: propsDict – the ammonia synthesis rate of Dyson & Simon (1968), on the bench. The law itself is constant/reactions' 'ammoniaSynthesis', every number of it written there ('type expression;'); this file only says where to evaluate it and what to print. Two questions, and they are different questions.

THE LOCUS. Sweeping temperature at a FIXED conversion locates the temperature of greatest net rate. Three conversions locate three points of the locus, and the point is that it DESCENDS. The conversion is of N2, walked from the paper's own reference mixture (3:1 H2/N2, 12.7 % inerts) along the reaction's stoichiometry. The sweep runs 600-900 K because that is roughly the band an iron catalyst lives in; at the lowest conversion the maximum is pushed ONTO the window's upper edge, and the bench says so rather than reporting an edge as a maximum.

THE DECLARED STATES. Three gases TRANSCRIBED from the converged answer of tutorials/steady/reactors/ammonia03_quench_converter, at the digits that case's own golden pins. A transcription is a SECOND HOME for somebody else's number and it will go stale if that case moves, so 'check_ammonia_rate' RUNS ammonia03 and holds these three blocks to its converged result.

The catalyst particle is the law's own parameter ('dp 8 mm;' in constant/reactions), inside the 6-10 mm range Eq 39 was fitted for; the law REFUSES one outside it.

tutorials/steady/reactors/ammonia03_quench_converter builds a three-bed quench converter out of equilibrium beds and then says, in its own README, what it cannot do: it cannot size a bed, it cannot tell a good injection point from a bad one, and it rewards over-quenching into a region where a real catalyst is too slow to reach the equilibrium the model hands it. All three gaps are the same gap — there is no rate law.

This case is the rate law — and since 2026-10-12 (DEV.md 4c C67) the law is WRITTEN here, in constant/reactions, every constant with its unit and its equation number, as kinetics { type expression; }. The engine compiles it once, checks its dimensions, prints it back as PARSED (the top of the run log), and the rateLawBench op evaluates it. Nothing about ammonia is compiled into the engine; the paper's anchors live in a gate.

The source. D. C. Dyson and J. M. Simon, ∗A kinetic expression with diffusion correction for ammonia synthesis on industrial catalyst∗, Ind. Eng. Chem. Fundam. 7 (1968) 605–610. Equations 2, 6–8, 18, 19, 39 with Table I, and 40.

Nothing in this case is measured by Choupo: the data these equations were fitted to are Nielsen, Kj?r and Hansen's (J. Catalysis 3 (1964) 68).

The same two letters, meaning opposite things. This case keeps the paper's convention because every number in it is read off the paper's own equations, and the engine says so at every surface that prints either letter. Carry η across from the reactor side and you will read a conversion as an effectiveness factor.

A correlation in this tree carries three things a reader can check, and this one carries them in the CASE:

rate01_arrhenius_recovery

tutorials/props/kinetics/rate01_arrhenius_recovery

What it does: Second-order decay at three temperatures, generated from k0 = 4e6, Ea = 60 kJ/mol: the Arrhenius line must give both back

The story: THE ACTIVATION ENERGY COMES OUT OF A SLOPE.

'kinetics1D' is a PROPERTY evaluation, not a reactor: it uses the integrated rate law in closed form, so a student can overlay competing orders on the same lab data and SEE which one is straight. Given isotherms at more than one temperature it goes further – fits k on each one, then the line

ln k = ln k0 - (Ea/R) (1/T)

and Ea falls out of the SLOPE. That is the whole of Arrhenius, and it is worth watching happen on data whose answer is known.

So the data here is generated from k0 = 4.0e6 L/(mol s), Ea = 60 kJ/mol, second order, at 40/60/80 C. The fit must return those two numbers; the expected file pins them, and R2 = 1 because the points carry no scatter.

What to read: the per-isotherm k values (3.93e-4, 1.57e-3, 5.34e-3), which span a factor of 13.6 over 40 K – the reason a rate constant is never quoted without its temperature.

Why the case exists: 'kinetics1D' had NO case and no gate. Its sibling vaporPressureFit was in the same position, and writing the first case for THAT one segfaulted choupoProps twice.

What to expect (golden-locked):

membrane

dspmde01_water_treatment_salts

tutorials/props/membrane/dspmde01_water_treatment_salts

monovalentWater	mixedWater	hardWater
poreTransport	poreTransport	poreTransport

What it does: A water-treatment feed through the DSPM-DE pore: nitrate, fluoride, bromide, carbonate and ammonium salts from the standard catalogue, on NanoFiltran's worked-example pore and the catalogue's NF270 archetype – every ion's radius and D0 cited on its species record

The story: THE RESEARCHER'S PATH, PROVED: a water that carries nitrate, fluoride, bromide, carbonate and ammonium, fed as SALTS from the standard catalogue, through the DSPM-DE pore (DEV.md 4c C157/C161/C170).

WHAT KIND OF CHECK THIS IS. A STRUCTURAL witness, not a validation. It shows that every one of these salts decomposes into its ions and that every ion finds a CITED hydrated radius (Nightingale 1959, Table I) and a CITED D0 (USGS PHREEQC phreeqc.dat, '-dw') on its species record, so the pore can be solved. No number here is a measurement. The two pores are NanoFiltran's worked example (constant/assets/NanoFiltranExample.dat, which describes no real membrane) and the catalogue's NF270_dspmde (an archetype whose pore is set, not fitted to this water): a researcher replaces them with the record his own fit writes (tutorials/steady/membranes/membrane24_fit_then_simulate is the template).

WHAT IS NOT HERE, AND WHY. Bicarbonate (HCO3-), phosphate and the hydrogen phosphates have a PHREEQC D0 but NO hydrated radius: Nightingale's Table I does not list them, and a Stokes radius from D0 is a different convention that would shift every steric hindrance in silence – so DSPM-DE REFUSES them by name (DEV.md 4c C161). NaHCO3 in this feed would stop the run with that refusal. The carbonate below is the CO3– of Na2CO3 taken fully dissociated: nothing here speciates it, so it stands for a high-pH water; at a natural pH most of it would be bicarbonate.

THE THREE OPERATIONS, each a 'poreTransport' bench at an IMPOSED J_v, ideal activities, NanoFiltran's "no polarisation" film (k = 10 m/s), the solved pore at 801 nodes: monovalentWater on NANOFILTRAN'S WORKED-EXAMPLE pore (X -30 mol/m3, r_p 0.40 nm, 2.5 um, eps_p 60): NaCl 5, NaNO3 1, NaF 0.5, KBr 0.5, NH4Cl 0.5 mol/m3 (Na K NH4 Cl NO3 F Br) mixedWater the same water plus Na2CO3 0.5 mol/m3 (+ CO3–), on the catalogue's NF270_dspmde pore (r_p 0.60 nm, X -5 mol/m3) hardWater Ca(NO3)2 2, KNO3 2, MgCl2 1, NaBr 1, MgSO4 1 mol/m3 (Ca Mg K Na NO3 Cl Br SO4), on NF270_dspmde WHY TWO PORES. NanoFiltran's example pore was set against NanoFiltran's own ion database, whose radii are STOKES radii (Na+ 1.84, Cl- 1.21, SO4– 2.31 A; nanofiltran_geraldesAlves2008/constant/species/). Against the catalogue's HYDRATED radii a 0.40 nm pore nearly closes to the divalent ions: lambda = r/r_p is 0.985 for CO3–, 0.95 for SO4–, 1.03 for Ca++ and 1.07 for Mg++. Measured 2026-10-26: Na2CO3 (alone, or in this water) and MgSO4 + NaCl do NOT converge there (the solved pore refuses, naming the stalled continuation), and MgCl2 or Ca(NO3)2 alone are refused because no cation enters the pore. So the divalent waters run on NF270_dspmde, whose 0.60 nm pore is the one its record states is consistent with the hydrated-radius tier. A pore and its ion radii are ONE convention: a pore fitted on one cannot be read with the other.

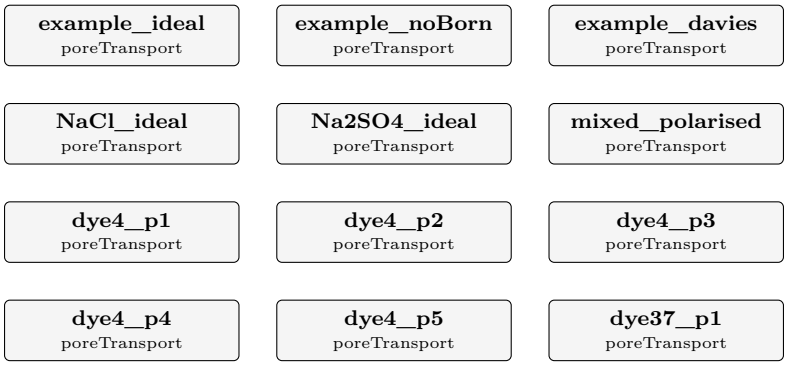
A water-treatment feed carries more than sodium chloride: nitrate, fluoride, bromide, carbonate, ammonium, calcium, magnesium and sulfate. A case feeds them as salts — each a component record with an ion map (dissociatesTo) — and the DSPM-DE pore works ion by ion: every ion needs its hydrated radius (steric partition and hindrance) and its free-solution diffusivity D0 (diffusion and convection in the pore).

This case proves that path end to end from the standard catalogue. Its salts are the standard records NaCl, NaNO3, NaF, KBr, Na2CO3, NH4Cl, calciumNitrate (Ca(NO3)2), KNO3, MgCl2, NaBr and MgSO4 (sealed into constant/components/ by bin/choupo-import, so the case is self-contained), and every ion resolves:

∗ its hydrated radius from Nightingale, J. Phys. Chem. 63 (1959) 1381, Table I (column r_H, 25 °C), read back against the primary page; ∗ its D0 from the public-domain USGS PHREEQC database phreeqc.dat, the 25 °C Dw of its -dw line.

Each species record (constant/species/<ion>.dat) cites its page, table, database line and file hash in its own transport { provenance {} } block.

Three operations, each a poreTransport bench at an IMPOSED permeate flux (J_v = 1e-6, 5e-6, 2e-5 m/s), ideal activities, no polarisation:



Each publishes, per J_v and per ion, the bulk, wall and permeate concentrations and the observed and real rejections. At 2e-5 m/s, for example, mixedWater rejects CO3– at 0.99985 and NO3- at 0.741, and hardWater rejects SO4– at 0.99989 against Cl- at 0.778 and Br- at 0.767 – the divalent co-ion held back by the negative pore, as NF does.

nanofiltran_geraldesAlves2008

tutorials/props/membrane/nanofiltran_geraldesAlves2008

What it does: The NanoFiltran paper (Geraldes & Alves 2008) in one case: Choupo against NanoFiltran code to code, against Bowen & Mohammad's MEASURED CA30 rejections (Fig. 3) and on the stiff case of Table 2 and Fig. 4 – its tables and figures generated by the views of its propsDict

The story: V. Geraldes, A.M. Brites Alves, "Computer program for simulation of mass transport in nanofiltration membranes", J. Membr. Sci. 321 (2008) 172-182 (doi:10.1016/j.memsci.2008.04.054) — NanoFiltran, and the two comparisons its paper makes, run by Choupo's DSPM-DE pore in one case.

Where the theory is

The model and the method are the Theory Guide's DSPM-DE chapter (section 19): the whole boundary-value problem one pore solves — the extended Nernst-Planck equations, electroneutrality at every node, zero current, the steric, Born and Donnan partitions at both faces, the multi-ionic wall — in 19.3; the Peclet numbers that decide how hard it is in 19.4; the numerical method (Scharfetter-Gummel fluxes, the block-tridiagonal Newton, the local Donnan seed, the continuation in J_v) in 19.5; and the node counts below, with what they mean, in 19.8. In the GUI, F1 on any operation of this case opens that chapter at the model, with the numerical method offered beside it.

What this case imposes, and what it computes

It IMPOSES the permeate flux J_v; it does not compute the flux from the pressure. Every operation is a poreTransport bench: it is handed J_v (a list; in study B, Bowen & Mohammad's fitted function evaluated at each operation's feed and written in the operation) and solves the extended Nernst-Planck equations across the pore, with electroneutrality at every node, steric, Born and Donnan partitions at both faces and the multi-ionic film at the wall. So the membrane record's A_w (the pure-water permeance, J_w = A_w (dP - dpi)) is carried because the record grammar requires it and is not read here.

What it publishes, per J_v point and per ion: the bulk, wall and permeate concentrations, the observed rejection R_obs = 1 - c_p/c_b and the real rejection R_real = 1 - c_p/c_wall, the potential across the membrane and the pore Newton's iteration count.

The three studies: what each teaches, and which one is stiff

Whether a pore is stiff is read off one number per ion, its pore Peclet number Pe_i = K_c,i J_v / (K_d,i D_i A_k/dx) — convection against hindered diffusion across the layer — computed here from the case's own ion records and membranes.

- A — Code to code: Choupo against NanoFiltran on one model. The same DSPM-DE model and the same inputs, solved by two independent programs (NanoFiltran: Fortran 77, central differences, under-relaxed Newton; Choupo: C++, exponentially fitted fluxes, full Newton). It teaches that the equations are solved right — the two programs' grid limits agree within 8e-7 on 35 permeates — and it is NOT a validation: no number here is a measurement, and the membrane is NanoFiltran's worked example, which describes no real membrane. The pore runs from nearly linear (J_v 1e-6 m/s, Pe of Mg2+ 0.7) to stiff (5e-5 m/s, Pe of Mg2+ 33).
- B — Experiment: Bowen & Mohammad's CA30 rejections (the paper's Fig. 3). It teaches what agreement with measurements means when the inputs were FITTED to those very data by Bowen &

Mohammad (AIChE J. 44 (1998) 1799): the pore radius and thickness, the membrane charge as a function of the feed (Eq. 43) and the permeate flux as a function of the feed (Eqs. 44-45). Agreement here says the pore model, carried by inputs fitted on these data, reproduces them — not that it predicts a membrane it was not fitted on. This study is NOT stiff: Pe is 0.06-0.14 for Na+ and 0.03-0.07 for Cl-, and the pore profiles are nearly straight. Its physics is at the WALL: the trivalent dye is as large as the pore (lambda = 1), so the pore excludes it; it accumulates in the film and sets the wall's electroneutrality, and that is what drives Cl- to R_obs = -2.

- C — The stiff case of Table 2 and Fig. 4, and its grid study. A numerical study, nothing measured: the paper's "very stiff" pore solved on six node counts, and Choupo's answer against Table 2 accounted for one change at a time. It IS stiff: Pe is 33 for Mg2+ against 0.56 for Na+ and 0.20 for Cl-, because the two counter-ions' hindered diffusivities K_d D differ 70 times (Mg2+ at lambda = 0.875 barely diffuses). Mg2+ is carried, the trace Na+ diffuses, and the pore holds an interior front where Na+ hands the fixed charge over to Mg2+ (Na+ falls from 12 to 0.16 mol/m3 between a third of the way in and the permeate face). The run prints the stiffness — the electromigration flux against the net flux — as 1.65e3 for every node count.

How many nodes: it depends on what you report

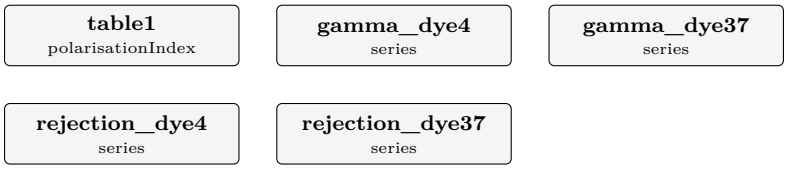
Measured on study C (re-run 2026-10-25 on a copy of this case whose six N operations were joined by 801 and 1601 nodes, every operation writing its pore profile). Errors against the case's finest grid, 350 nodes, which is itself within 1e-4 relative of the Richardson limit of 801 and 1601 nodes on every row:

quantity (value at 350 nodes)	10 nodes	20	50	100	200
R_obs of Na+ (99.4457 %), in points	-0.073	-0.017	-0.0025	-0.0006	-0.0001
permeate Na+ (0.05543 mol/m3)	+13.2 %	+3.03 %	+0.45 %	+0.10 %	+0.019 %
permeate Mg2+ (8.6317 mol/m3)	-0.64 %	-0.15 %	-0.023 %	-0.005 %	-0.001 %
permeate Cl- (17.3188 mol/m3)	-0.59 %	-0.14 %	-0.021 %	-0.005 %	-0.001 %
Mg2+ at the pore's permeate end (15.0235 mol/m3)	-0.077 %	-0.018 %	-0.0026 %	-0.0006 %	-0.0001 %
psi at the pore's permeate end (0.07217 V)	-4.52 %	-1.08 %	-0.16 %	-0.038 %	-0.007 %
potential across the membrane, dPsi_m (0.14496 V)	-2.21 %	-0.53 %	-0.080 %	-0.018 %	-0.003 %
Newton iterations (12 at 350 nodes)	7	9	9	10	11

The lesson: the rejection forgives a coarse grid; the permeate of a trace ion — and so any selectivity built on it — does not. Ten nodes put the Na+ rejection within 0.1 point and its permeate 13 % high. The error falls as the square of the cell size (double the nodes, a quarter of the error), so declare nodes at n and 2n and compare the quantity you report.

Read the comparisons for what they are

- Nothing was fitted by this run. In study B the parameters were fitted by Bowen & Mohammad, before this case existed; Choupo fits nothing.
- The error bars of Fig. 3 are READING uncertainty. The measured symbols were digitised from the paper's figure (calibration checked against the tick labels; reading error +-1.5 px = 0.32 mol/m3 in c_Cl and 0.011 in R_obs). They are not the original experimental uncertainty.
- The feed chloride of each study-B operation is the mean of its two markers' readings — the Na+ and Cl- symbols of one measurement sit at one feed, and were read at slightly different abscissae.
- The two programs count N differently. Choupo's N nodes have N - 1 intervals; NanoFiltran's N counts the permeate node, so it has N - 2 intervals inside the membrane.
- Table 2 carries a factor of ln 10 in its Davies activities, and Choupo deliberately reproduces no such option, so Choupo is NOT pinned to Table 2: it is pinned to NanoFiltran with that constant (and its Born constant and diffusivity input) corrected. The grid-study figure's "Davies corrected" NanoFiltran line has ONLY the Davies constant corrected, so the gap left between it and Choupo is not discretisation alone.
- 12 against 88 iterations is not a speed measurement. Choupo runs a full Newton with an analytic Jacobian to its own tolerance; NanoFiltran an under-relaxed (0.2) Newton to TOL 1e-4. The criteria, the relaxation and the work per iteration differ.



The full account — every difference between the two programs and how each was handled, the Davies finding, and the term-by-term accounting of Table 2 — is the leading comment of system/propsDict.

polarisation01_geraldes_afonso_table1

tutorials/props/membrane/polarisation01_geraldes_afonso_table1

What it does: Concentration polarisation of a Na+/Cl-/dye3- solution (Geraldes & Afonso 2007, Table 1): per-ion k, one interface field, Gamma per ion – no film thickness

The story: polarisation01 – THE CONCENTRATION POLARISATION OF A MULTI-IONIC SOLUTION, computed the way Geraldes & Afonso did it (J. Membr. Sci. 300 (2007) 20-27, doi:10.1016/j.memsci.2007.04.025) for the case study of their Section 2.2: nanofiltration of Na+ / Cl- / dye3- solutions in a stirred cell (experimental data of Bowen & Mohammad, AIChE J. 44 (1998) 1799).

THE QUESTION. How much does each ion pile up at the membrane wall when three ions of different diffusivities and charges are rejected to different degrees? The classical film model cannot answer it: it needs ONE effective diffusivity for the solution, and a mixture of ions has none. The extended Nernst-Planck approach answers it only after choosing a film thickness, which nobody measures.

THE MODEL. At the feed-solution/membrane interface, for every ion, the flux J_v C_p equals back-diffusion plus convection plus MIGRATION in the electrical potential gradient xi that the ions' different mobilities set up (Eqs. 2-7); electroneutrality at the interface (Eq. 8) fixes xi. The mass-transfer coefficient of each ion comes from the cell's conventional correlation on the ion's OWN diffusivity, Sh_i = 0.23 Re^0.567 Sc_i^0.33 (Bowen et al. 1997), corrected for the suction effect of the permeation by Xi_i = phi_i + (1 + 0.26 phi_i^1.4)^-1.7 (Geraldes & Afonso 2006). Four algebraic equations per operating point (Eqs. 25-28), NO film thickness, NO new parameter.

WHAT TO READ IN THE OUTPUT. The polarisation index Gamma_i = (C_m - C_b)/C_b per ion and per row – the open symbols of the paper's Fig. 7. The dye (slowest, most rejected) polarises most; Na+ is dragged along by the field; Cl-, less rejected than the dye and pulled by the same field, shows a NEGATIVE Gamma at the low Cl- feeds – its wall concentration is BELOW the bulk, which the film model applied ion by ion cannot produce. The residual sum z_i C_m,i / sum |z_i| C_m,i printed under each row is the electroneutrality the field enforces.

WHAT IS AND IS NOT MEASURED. C_b, C_p and J_v are the table's; Na+ is derived from electroneutrality as the table's own footnote says. The Gamma are PREDICTIONS of the model from those inputs and the ions' D – nothing is fitted. The paper compares them with an extended Nernst-Planck integration in the dye's film (its Fig. 7, filled symbols), which this case does not reproduce.

The gate check_polarisation_coupling recomputes the same four equations in Python from this case's own data file and holds every Gamma to 1e-8.

The question. Three ions – Na+, Cl- and a trivalent dye – are nanofiltered in a stirred cell. The dye is rejected almost completely, the chloride barely. How much does each pile up at the membrane wall?

The lesson. Geraldes & Afonso, J. Membr. Sci. 300 (2007) 20-27 (doi:10.1016/j.memsci.2007.04.025), answer it with four algebraic equations per operating point and NO film thickness: the cell's conventional correlation Sh_i = 0.23 Re^0.567 Sc_i^0.33 on each ion's OWN diffusivity, the suction correction Xi_i = phi_i + (1 + 0.26 phi_i^1.4)^-1.7, and one electrical potential gradient at the interface fixed by electroneutrality at the wall. The polarisationIndex bench prints, for each of the ten rows of the paper's Table 1 (data of Bowen & Mohammad, AIChE J. 44 (1998) 1799), the per-ion k, phi, Xi, wall concentration, polarisation index Gamma_i = (C_m - C_b)/C_b and the field xi – the open symbols of the paper's Fig. 7. The dye (slowest, most rejected) polarises most; Na+ is dragged after it by the field; Cl- sits BELOW its bulk concentration (negative Gamma), which the film model applied ion by ion cannot produce.

Headline numbers (Gamma): row 1 (dye 4, Cl 5.2 mol/m3) dye +0.504, Na +0.310, Cl -0.137; row 10 (dye 37, Cl 87.3) dye +0.273, Na +0.120, Cl -0.074. Re = 26906 against the paper's 26907.

The figures. The run draws them (the GUI's review screen opens on them). The op publishes its DEFAULT views with nothing declared – Gamma of every ion row by row, the rejection the cell MEASURES (1 -

C_p/C_b, from Table 1) beside the one the membrane makes (1 - C_p/C_m, Choupo's wall), and Table 1 row by row with Gamma_i and the field – and the propsDict's views split the same rows by dye level and draw them against the feed chloride at 4 and at 37 mol/m3 of dye (the paper's Fig. 7, open symbols). Every number is the bench's published rows table; the paper's own Gamma values are not in the tree, so none is drawn as if it were.

What is measured and what is not. C_b, C_p and J_v are the table's; Na+ is derived by electroneutrality as the table's footnote says (closeBy Na;). Every Gamma is a PREDICTION from those inputs, the ions' D and the correlation; nothing is fitted. The paper's filled symbols (an extended Nernst-Planck integration in the dye's film) are not reproduced. The dye is a case-local species (constant/species/dye.dat, z = -3, D = 0.36e-9 from the paper's footnote); the sources do not identify the compound, so its MW is a flagged nominal placeholder that nothing here reads.

The gate. check_polarisation_coupling re-solves Eqs. 25-28 in Python from this case's own data file and holds every Gamma AND xi to 1e-8, holds a single salt to the paper's closed form Eq. 20, and holds the filmTheory + none policy to the classical film model to round-off.

shortlist01_class_to_modules

tutorials/props/membrane/shortlist01_class_to_modules

What it does: From a membrane class to the commercial elements that do it: hard filters, each survivor re-rated at the student's conditions, every criterion side by side, no score

The story: shortlist01 – THE SHORTLIST (DEV.md 4c C189 slice 5): from a membrane class to the commercial elements that do what the class does.

THE QUESTION. membrane26 chose a membrane by WHAT IT DOES (NF_DIVALENT_SELECTIVE: hold sulphate, let sodium chloride through). Which products in the catalogue do that, at MY pressure, MY temperature, MY feed and MY recovery – not at the data sheet's?

WHAT THE OP DOES. (1) Hard filters on each module record: the membrane is of the class's type (NF here), the record carries ONE rated test of MgSO4, the sheet's rated rejection lies inside the class's band (>= 90 %), the declared limits hold at this feed. (2) Each survivor is re-run with the transport law and film of the 'operation' block below, its intrinsic rejection DERIVED from its OWN rated test (slice 1), at the conditions below, with the feed flow found so ONE element delivers the recovery asked. Then the limits that need the run (feed flow, pressure drop) filter again.

WHAT IT DOES NOT DO. It scores nothing and ranks nothing. Every criterion is published side by side, the candidates in alphabetical order of their names, and a record's commercial-relation fields ('partner', 'dataVerifiedBy') are never read. What matters most – permeate flow, permeate quality, specific pressure – is the student's decision.

WHAT TO READ. The printed rows (and shortlist.csv): permeate flow and concentration, flux, P/flux (bar per L/m2/h), the hydraulic energy per m3 of permeate (feed pressure x feed flow / permeate flow, no recovery device), the feed flow, the element's pressure drop and each limit's margin ((limit - value)/limit; pH in pH units; "n/s" = the record states no such limit). EXCLUDED rows say why, in the record's own numbers.

The question. membrane26 chose a membrane by what it DOES (NF_DIVALENT_SELECTIVE: hold sulphate, let sodium chloride through). Which products in the catalogue do that – at MY pressure, MY temperature, MY feed and MY recovery, not at the data sheet's?

The op. membraneShortlist (DEV.md 4c C189 slice 5). It does two things and nothing else.

1. ∗Hard filters∗, on each module record: the membrane is of the class's type (NF here), the record carries ONE rated test of the asked solute, that test's rated rejection lies inside the class's band, the declared limits (P_max, T_max, pH) hold at the student's feed. A limit the record does not state is not a filter (n/s). 2. ∗Re-rating∗: every survivor is re-run with the film and spacer of the operation block, its intrinsic rejection DERIVED from its OWN rated test (slice 1), at the student's conditions, with the feed flow found so ONE element delivers the recovery asked. The limits that need the run (feed flow, pressure drop) then filter again.

What it will not do. Score, weight or rank. Every criterion is printed side by side (permeate flow, observed rejection, permeate concentration, flux, P/flux, hydraulic energy per m3, feed flow, pressure drop, margins to each limit), the candidates in alphabetical order of their names, and what matters most is the student's decision. A record's commercial-relation fields (partner, dataVerifiedBy) are never read: the gate proves it.

What to expect here. tiers (standards case) keeps the golden independent of one machine's private data/local/assets/ records (the importer's home); drop the line and an imported catalogue joins the table, each of its records announced [local] UNVERIFIED. Of the shipped records NF270-4040 passes; SW30HR-380 is excluded (an RO membrane, rated on NaCl); the Generic elements are excluded (they carry no rated test).

Read it with care. The re-rating is the transport law of a lumped salt with its intrinsic rejection fixed at the sheet's ONE test – a model's reading of a data sheet away from its test, not a guarantee of the product.

What to expect (golden-locked):

... and 10 more reference values in the case's `expected`.			

molecular

The theory you need. Molecular activity models on display: NRTL/Wilson/UNIQUAC correlate binary γ's from pair parameters; UNIFAC PREDICTS them from group counts. Expect UNIFAC within a few percent of fitted models for families it was trained on – and to be honestly worse outside them. *Full derivation: Theory Guide, the activity-model chapter.*

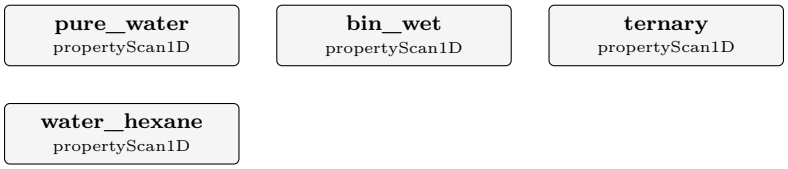
componentLookup01_catalogue_ladder

tutorials/props/molecular/componentLookup01_catalogue_ladder

What it does: componentLookup: a catalogue record by name and by CAS, a group-estimate-lake compound, and an unknown

The story: WHAT IT IS. "Does Choupo have this compound, and what does its record carry?" as ONE operation with a fixed byte budget (2048 bytes) and the same evidence-card format as pairLookup (DEV.md 4c C227, slice a). The query resolves by RECORD – a catalogue file name, a declared alias or a CAS – never by name similarity. Four operations:

c_name ethanol the catalogue record, by name c_cas 64-17-5 the SAME record, by CAS c_lake 1Pentadecanol only in the group-estimate lake: identity and UNIFAC groups, NO values, "not reviewed" c_none unobtainium "I do not have this compound"



The card lists which properties the record has and which it lacks; it never prints the values (they are in the record, and a case uses the name). Pinned: the tier word of each card and its byte count. The thermoPhysPropDict is a placeholder the bench requires; no op reads it.

What to expect (golden-locked):

diag	water_hexane	n_emptyCurves	0

entropy01_air_ledger

tutorials/props/molecular/entropy01_air_ledger

What it does: The entropy ledger of 79/21 N2/O2 at 400 K, 2 bar on SRK: every line of s(T,P,y) published separately, so a reader can rebuild the total by hand

The story: THE ENTROPY LEDGER, published line by line – the witness behind the "What is entropy?" EduTool page.

The engine's mixture entropy is assembled in ThermoPackage::S_ig (src/thermo/ThermoPackage.cpp) as

S_ig(T,P,y) = sum_i y_i ∗ s_ig_i(T) (pure-state line) - R ∗ sum_i y_i ∗ ln y_i (mixing line) - R ∗ ln(P / 1 bar) (pressure line)

with each s_ig_i(T) = s_298_i + integral Cp_i/T dT off the component's own .dat (Component::s_formation), and S_real = S_ig + S_residual(SRK) (the model line, Sandler eq. 6.4-31). The 'ledger' op below publishes the per-component s_ig_i AND the assembled S_ig / S_R / S_real at one state, so a reader – or the EduTool page in the browser – can rebuild the total from the lines and check it against the engine's own number. The two scans draw the temperature line (integral Cp/T at fixed P) and the pressure line (-R ln P at fixed T, with the residual gap growing).

Nothing here is a validation against measurement: every number is the engine's own answer, decomposed. The value of the case is that the decomposition CANNOT drift from the simulator, because it is published by the same call that computes it.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	ledger	Cp_ig	29.46367008
diag	ledger	H_R	-5.48583758685

. . . and 36 more reference values in the case's `expected`.

envelope01_natural_gas

tutorials/props/molecular/envelope01_natural_gas

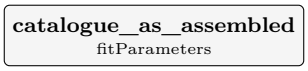
What it does: P-T phase envelope of a lean natural gas: the dew branch over its cricondentherm, and a bubble branch that never starts

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	envelope	bubble_points	0
diag	envelope	bubble_stopped_bar	1
diag	envelope	dew_cricondentherm_K	275.946403666
diag	envelope	dew_points	40

envelope02_c3c4c5_branch_stop

tutorials/props/molecular/envelope02_c3c4c5_branch_stop



What it does: P-T envelope of a C3/C4/C5 feed marched through propane's Tc: the reference factor is held continuous above 0.99 Tc, so both branches cross Tc; with the cubic's vapour pseudo-root both reach 40 bar (C245), and no cricondentherm is claimed

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	envelope	bubble_points	40
diag	envelope	dew_points	40

eval_nrtl_catalogue

tutorials/props/molecular/eval_nrtl_catalogue

What it does: EVALUATE mode: score the CATALOGUE NRTL pair against your own data – the scale before any fit

The story: ‘mode evaluate‘: the SCALE, not the fit.

ONE operation, one question: how good is the ethanol-water NRTL pair against this 1-atm bubble-T dataset? Nothing is adjusted, nothing is written. The thermoPhysPropDict declares NO inline pairs, so what gets scored is a REAL provenance-bearing pair resolved through the search path (from this case's own vendored constant/parameters/ copy, identical parameters and full primary citation) – not numbers typed inline into the dict.

Read the verdict (rms/aad in kelvin) and THEN decide whether a refit is worth it: compare with fitNRTL01's fitted rms (0.31 K) on this same data. Failures are honest: a non-converged point becomes status=nonconverged in the parity CSV and never enters the statistics; no chi2_reduced is printed – without sigmas and degrees of freedom from THIS act, the name would lie.

The pinned-what-if grammar and the leakage sentinel live in the sibling case eval_nrtl_pinned (a pinned path must EXIST in the dict, so what-ifs run on an INLINE scaffold and say so).

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	catalogue_as_assembled	aad	2.0400
diag	catalogue_as_assembled	chi2	60.1945

diag	catalogue_as_assembled	sse	60.1945
diag	catalogue_as_assembled	validity_declared	1.0000
diag	catalogue_as_assembled	n_outside_validity	0.0000

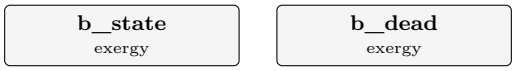
eval_nrtl_pinned

tutorials/props/molecular/eval_nrtl_pinned

What it does: EVALUATE a pinned what-if: a pinned run scores the package but mutates NOTHING (the leakage sentinel)

The story: the pinned WHAT-IF, and the LEAKAGE SENTINEL.

TRANSITIONAL SCAFFOLD: pinning by dict path requires an inline pair; the permanent surface (ParameterOverrides on the RESOLVED parameter registry, design forum #67/#69) replaces this case when it lands.



Three evaluations of the same dataset: 1. scaffold_as_is – the inline pair, untouched (the baseline). 2. rough_paper_values – the SAME dict with four coefficients PINNED to deliberately rough values. The pin operates on a DEEP COPY (Dictionary::deepCopy, forum #63-7); nothing on disk or in memory survives the op. 3. scaffold_again – repeats 1 AFTER the pinned run. Its verdict must be IDENTICAL to 1's: the golden pins both, so the working-tree isolation is guarded by the corpus forever. Before deepCopy existed, the old alias bug would make THIS operation report the rough values' score.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	scaffold_as_is	aad	2.0400
diag	scaffold_as_is	chi2	60.1945
diag	scaffold_as_is	max_abs_resid	3.4379

diag	rough_paper_values	max_abs_resid	5.5866
... and 21 more reference values in the case's `expected`.			

exergy01_air_dead_state

tutorials/props/molecular/exergy01_air_dead_state

What it does: Physical exergy of 79/21 N2/O2 at 400 K, 2 bar against a DECLARED 298.15 K / 1 bar dead state – b = (h-h0) - T0(s-s0) from the engine's own H_real/S_real, with the structural zero at the dead state itself as the second row

The story: PHYSICAL EXERGY, the number the entropy ledger buys – the witness behind the exergy work that follows the "What is entropy?" page.

b = (h - h0) - T0∗(s - s0), every term the engine's own H_real/S_real at the SAME composition, so the enthalpy datum, the s_298 anchors, the mixing term and the reference pressure ALL cancel: the exergy is datum-independent. The dead state is DECLARED (an exergy is a statement about a state AND an environment; the engine refuses to assume one).

Two rows on purpose: the same state the entropy01 ledger decomposes, and the dead state itself – whose exergy is 0 identically, by construction, which the golden pins as the structural zero.

Nothing here is validated against measurement: every number is the engine's own answer, decomposed. The published dh and T0ds legs re-add to b on the reader's desk.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	b_state	P	200000
diag	b_state	P0	100000
diag	b_state	T	400

diag	b_state	h	2980.68
diag	b_state	h0	-6.63211
diag	b_state	s	201.559
diag	b_state	s0	198.706
diag	b_dead	P	100000
diag	b_dead	P0	100000
diag	b_dead	T	298.15
... and 8 more reference values in the case's `expected`.			

flash01_operating_line

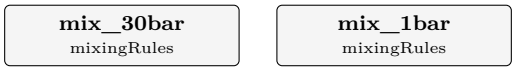
tutorials/props/molecular/flash01_operating_line

What it does: The equilibrium curve a flash operating line is drawn on

The story: THE CURVE, AND ONLY THE CURVE.

A binary flash is fixed by two of {T, P, V/F} – Duhem – so at a frozen pressure the equilibrium curve y∗(x) is frozen too. Everything the flash tool draws on top of it (the operating line, its intersection, the lever rule) is GRAPHICAL construction on this one table, which is why turning a knob there redraws at once instead of re-solving.

So this case publishes exactly one thing: the curve. It does NOT flash anything. The flash the student watches is the intersection, performed on these rows – and the corpus already carries the ENGINE's own answer for the same pair (tutorials/steady/flash/flash01_benzene_toluene, V/F = 0.30398 at 370 K), which is the number to check the construction against.



51 points is not a rounding of taste: the construction interpolates linearly between rows (no spline – an overshoot near an azeotrope would invent equilibrium the engine never computed), so the sampling IS the resolution of every answer read off it.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	txy	n_emptyCurves	0
diag	txy	n_failures	0
diag	txy	n_points	51

mixrules01_natural_gas

tutorials/props/molecular/mixrules01_natural_gas

What it does: The van der Waals one-fluid mixing rule, decomposed: SRK a_mix/b_mix of a 90/5/5 CH4/N2/CO2 gas at 250 K, pair by pair – the one curated kij (N2-CH4, DECHEMA) beside the pairs that run the kij = 0 default, and the same decomposition at 1 bar showing a_mix is a (T, y) fact while only A, B, Z carry the pressure

The story: THE MIXING RULE, DECOMPOSED – the multicomponent lesson. A cubic prices a MIXTURE through two numbers, and the one-fluid rule says how n pure components and n(n-1)/2 binary corrections build them:

a_mix(T) = sum_i sum_j y_i y_j (1 - kij) sqrt(a_i a_j) b_mix = sum_i y_i b_i

Every term is on the table: the six pair terms of this ternary re-add to the a_mix the flash would run (the op REFUSES if they do not), the curated N2-CH4 kij sits beside the two CO2 pairs running the announced kij = 0 default, and the pair table is where a student sees that a ternary needs THREE binary decisions – there is no ternary parameter.

Two states on purpose, same composition and temperature: a_mix and b_mix are IDENTICAL at 30 bar and 1 bar (the rule sees only T and y), while A, B and Z carry the pressure – at 1 bar the same gas is nearly ideal (Z ~ 0.997) and at 30 bar it is not (Z ~ 0.93), priced by the SAME two numbers through the cubic.

Nothing here is validated against measurement: every number is the engine's own arithmetic, decomposed. The one cited constant is the N2-CH4 kij record (Knapp et al., DECHEMA VI, 1982).

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	mix_30bar	A	0.140523
diag	mix_30bar	B	0.0428434

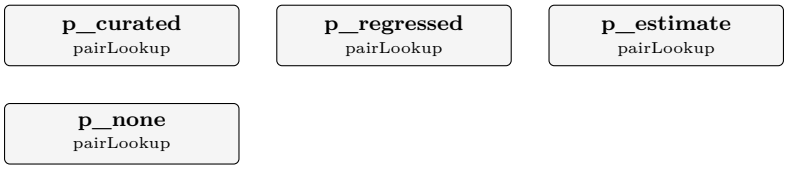
... and 46 more reference values in the case's `expected`.			

nrtl01_ethanol_water_package

tutorials/props/molecular/nrtl01_ethanol_water_package



What it does: ethanol-water NRTL via the SAME property-package builder (molecular U4)

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	g_nrtl	gamma_ethanol	1.26245
diag	g_nrtl	gamma_water	1.4349

pairLookup01_catalogue_ladder

tutorials/props/molecular/pairLookup01_catalogue_ladder

What it does: pairLookup: the honesty ladder for four pairs (curated, regressed, UNIFAC estimate, none)

The story: WHAT IT IS. The student's FIRST question about a binary – "what does Choupo have for this pair?" – asked as ONE operation that answers in a fixed byte budget (2048 bytes of card text, held by check_lookup_budget) with an EVIDENCE CARD, never a number invented to fill a gap. The four operations walk the honesty ladder (DEV.md 4c C227, slice a):

p_curated ethanol + water a catalogue pair record: the paste-ready source entry, validity, provenance p_regressed acetone + ethanol Choupo's own regression (fittedInCase, interim) with its held-out verdict p_estimate acetone + cyclo- no pair record, both carry UNIFAC hexane groups: SAID to be an estimate, with the measured warning (DEV.md C219) p_none 1Pentadecanol + a component only in the group-water estimate lake: "I do not have this pair"

HOW IT READS. The operations read the INSTALLATION catalogue (a question about the catalogue), never the case's own constant/. The card carries what the records carry today; what the C16 chain will add (laboratories, archive sha256, extraction filter, fit AAD) is listed under announcedAbsent and never filled. The rung "servable from the measurement archive but not yet fitted" is slice (b) and the card says it does not exist yet. Pinned: the TIER WORD of each card and its byte count; the numbers a card quotes live in the records, which have their own gates. The thermoPhysPropDict is a placeholder the bench requires; no op reads it.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	p_curated	budget_bytes	2048
diag	p_curated	card_bytes	947
diag	p_curated	n_records	2

verdict	p_curated	tier	curated
verdict	p_regressed	tier	regressed
... and 3 more reference values in the case's `expected`.			

pairLookup03_provenance_stale_seal

tutorials/props/molecular/pairLookup03_provenance_stale_seal

What it does: pairLookup provenance line: case sealed from an OLDER release than the installation

The story: WHAT IT IS. Witness of the PROVENANCE LINE every lookup card carries (DEV.md 4c C227 (a)) (the card carries a provenance line and the JSON a ‘catalogue‘ object).

THIS CASE: SEALED, and its manifest names Choupo-2607 – a legitimate old seal (the catalogue identity a seal records is the catalogue as it stood when the case was frozen; CATALOGUE.dat explains why 394 manifests keep that name) – while the installation is Choupo-2608. The lookups still read the installation, so the card is from a release that is NOT the case’s own, and the provenance line SAYS so: ‘case sealed Choupo-2607; differs "..."‘. The result JSON carries the same fact as ‘releaseDiffers true‘. Pinned: the tier word, the card bytes.

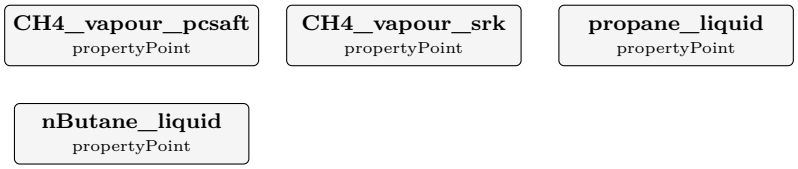
What to expect (golden-locked):

kind	unit/stream	key	expected
diag	p_curated	budget_bytes	2048
diag	p_curated	card_bytes	1039
diag	p_curated	n_records	2
verdict	p_curated	caseSeal	sealed
verdict	p_curated	releaseDiffers	true

pcsaft01_pure_nhexane

tutorials/props/molecular/pcsaft01_pure_nhexane

What it does: PC-SAFT pure n-hexane: Z + liquid molar volume at 298 K, 1 bar



The story: the NON-ASSOCIATING PC-SAFT core, validated on a pure n-alkane. n-hexane's segment parameters (m, sigma, epsilon/k) are the Gross & Sadowski 2001 Table 1 fit; the case evaluates the compressibility factor Z and the liquid molar volume at 298.15 K / 1 bar and locks them as a golden. The engine PROVES the model self-consistent on every run (PCSAFT::verify: a_res → 0 in the ideal limit, and the residual chemical potentials reproduce the bulk residual Gibbs energy to ~1e-9). Physical cross-check (see README): the PC-SAFT liquid density here is ~650 kg/m3, within ~0.8 % of the ~655 kg/m3 experimental value.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	liquid_298K_1bar	Cp_ig	1.43106e+02
diag	liquid_298K_1bar	H_R	-3.91460e+02

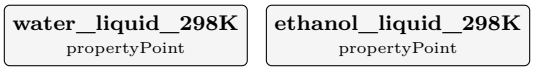
pcsaft02_states_crosscheck

tutorials/props/molecular/pcsaft02_states_crosscheck

What it does: PC-SAFT across states: CH4 Z vs SRK cross-check + propane/n-butane liquid density vs handbook

The story: PC-SAFT validated ACROSS STATES and AGAINST AN INDEPENDENT MODEL, before the model is trusted in a flowsheet.



Three probes, all goldened: (1) CH4 vapour Z at 300 K / 50 bar – PC-SAFT vs SRK at the SAME state (the per-op 'thermo {}' override): two independently-validated models must agree closely for a simple near-spherical vapour, and the run prints both so the student SEES the agreement (not told to assume it). (2) propane compressed liquid at 298.15 K / 15 bar – rho_liq vs the saturated-liquid handbook value (0.493 g/mL at 25 degC). (3) n-butane compressed liquid at 298.15 K / 5 bar – rho_liq vs 0.573 g/mL at 25 degC. Deviations sit at the 1-2 % liquid-density AAD Gross & Sadowski 2001 (Table 2) report for the n-alkane series – these parameters PREDICT the density; it was never refitted here.

What to expect (golden-locked):

kind	unit/stream	key	expected

pcsaft03_association_pure

tutorials/props/molecular/pcsaft03_association_pure

What it does: PC-SAFT association (Wertheim TPT1): 2B water + 2B ethanol, pure liquids

The story: PC-SAFT WITH ASSOCIATION (Wertheim TPT1; Gross & Sadowski, Ind. Eng. Chem. Res. 41 (2002) 5510) – the hydrogen-bonded liquids the non-associating core cannot represent, as PURE liquids at 298.15 K, 1 bar.

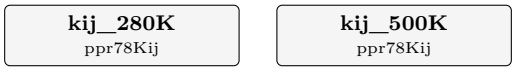
The association parameters live on the component records (2B water, 2B ethanol – both G&S 2002 Table 1, fitted WITH the association term; the paper lists water with TWO sites, and the scheme is PART of the fit: this same set mis-curated as 4C passed the pure-density check by coincidence and collapsed the ethanol/water mixture flash); the case only declares 'model PCSAFT;', and the engine announces the roster it found on the records:

[pcsaft] associating: water (2B), ethanol (2B); cross: Wolbach-Sandler

Liquid densities PREDICTED here (goldened), vs the CRC Handbook 25 degC values – each deviation stated against what the SET is fitted for:

water v_molar_liq → rho_liq = 921.9 kg/m3 vs 997.05 (-7.5 % – the PUBLISHED trade-off of the 2-site water fit, which is Psat-accurate instead: -0.2 % at 358 K, +4 % at 298 K) ethanol v_molar_liq → rho_liq = 779.8 kg/m3 vs 789.3 (-1.2 %)

What the student sees at verbosity 3 (the widened validation, ratified 2026-08-02): the construction-time verify() now ALSO echoes, per associating component as a pure fluid, the converged site fractions X^D / X^A, the a_assoc share, and the CLOSED-FORM-vs-ITERATIVE oracle deviation (for nD = nA the mass-action closure collapses to a quadratic; the damped fixed point must land on its root – observed machine zero). X^A(water) ~ 0.039: 96 % of water's sites are hydrogen-bonded at ambient conditions – the physics the term adds.



The two ops publish the standard vapour-root family (Z, v_molar) plus the labelled liquid root (v_molar_liq); at 1 bar both fluids carry a metastable vapour root beside the stable liquid.

ppr78Kij01_ch4_co2_h2

tutorials/props/molecular/ppr78Kij01_ch4_co2_h2

What it does: The E-PPR78 group-contribution kij of a CH4/CO2/H2 gas, evaluated once at a declared temperature and written as a kij SET record a phi-phi package reads: at 280 K every pair lies inside the T window of the data its group parameters were fitted on, at 500 K every pair is an extrapolation and the set says so pair by pair

The story: A kij FROM GROUPS, AT A DECLARED TEMPERATURE. A cubic needs one binary correction kij per pair, and a measured one exists for few pairs. PPR78 (Jaubert & Mutelet) predicts it from the GROUPS each molecule is made of:

k_ij(T) = [E_ij(T) - (delta_i - delta_j)^2] / (2 delta_i delta_j) delta_i = sqrt(a_i(T)) / b_i (Choupo's own PR78) E_ij(T) = -1/2 SUM_k SUM_l (alpha_ik - alpha_jk)(alpha_il - alpha_jl) A_kl (298.15 / T)^(B_kl / A_kl - 1)

so kij DEPENDS ON T. The 'ppr78Kij' op evaluates it ONCE, at the temperature it is told, and writes the matrix to a FILE – a kij SET record ('recordType eosBinaryInteractionSet;') that a phi-phi package then declares – with the three terms of the quotient beside every value, so the division can be redone by hand.

WHAT THIS CASE SHOWS. The same three pairs at two temperatures: 280 K: every pair (CH4-CO2, CH4-H2, CO2-H2) lies inside the T range of the binary data its group parameters were fitted on (Xu et al. 2017, Table 2) – nothing is marked; 500 K: every pair lies above that range, and the set writes 'extrapolated yes;' with the window on each of them. The components are each their own group, so alpha is 1 or 0 and E_ij is the single group-pair term.

THE GROUP TABLE is constant/parameters/PPR78/xu2017.dat, the E-PPR78 subset (Xu, Lasala, Privat & Jaubert, Int. J. Greenh. Gas Control 56 (2017) 126-154, Table 3); its own header explains its transcription and that it is 'reviewStatus interim'.

WHAT IS NOT VALIDATED. Nothing here is compared with a measurement: the numbers are Eq. 4 evaluated on the cited table and the engine's own PR78 a_i(T), b_i. Whether those kij reproduce a phase diagram is not asked here.

THE TWO SET FILES are run outputs: they carry the date they were written, so they are named '*.proposal.dat', which git ignores.

solubility01_hildebrand_ladder

tutorials/props/molecular/solubility01_hildebrand_ladder

What it does: Hildebrand: one number for like-dissolves-like, and where it stops

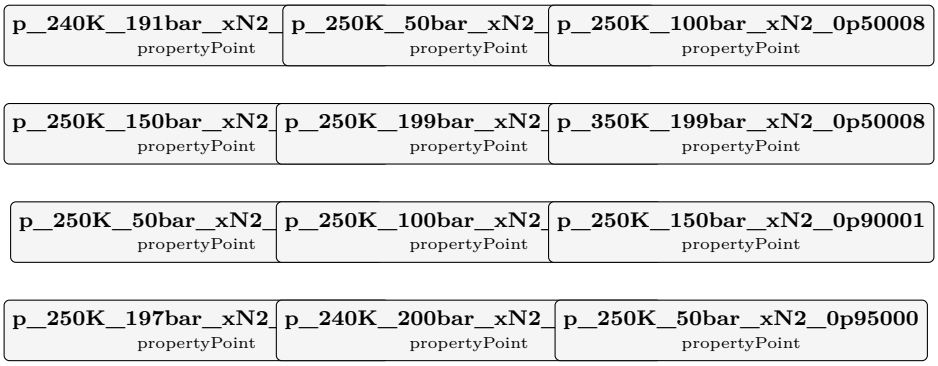
Seven liquids on a ladder of cohesive energy density, from hexane to water.

δ is derived, never stored: sqrt((ΔHvap(T) - RT)/V_m), with the latent heat from the Watson correlation the enthalpy legs already use. Every input is already in the component record, so a stored δ would be a second home for a fact the record fixes — free to drift from it.

The published column is an ∗anchor∗, not an input. It is what ChemSep computed independently, and its only job is to give the derivation something to be wrong against. Worst deviation here is 0.85 %.

That matters because the three ways this arithmetic fails are all silent:

∗ the RT term dropped — δ a few per cent high, and a solubility parameter has no intuitive magnitude to make that look wrong; ∗ V_m in the wrong unit; ∗ Pa^0.5 reported where the literature uses MPa^0.5 — a factor of 31.6, and the number still reads as a solubility parameter.



Same device as the Zc column in a property data bank: a redundant determination turns a plausible wrong number into a visible disagreement.

srk01_h2n2_density

tutorials/props/molecular/srk01_h2n2_density

What it does: Does SRK describe the ammonia synthesis loop's gas? Sixteen MEASURED (T, P, x, rho) points on the nitrogen + hydrogen binary – Hernandez-Gomez, Tuma, Gomez-Hernandez and Chamorro, J. Chem. Eng. Data (2017), doi:10.1021/acs.jced.7b00694 – evaluated with the same SRK the green-ammonia plant runs on, and with kij = 0 because the catalogue carries no N2-H2 pair. The engine computes the molar volume; the case's own evidence file carries the measurement; the comparison is the lesson.

The story: IS SRK GOOD ENOUGH FOR THE AMMONIA SYNTHESIS LOOP?

Vitor's question, 2026-09-09: "dadas as pressoes extremas a que isto funciona, achas que os modelos termodinamicos que estamos a usar sao razoaveis e estao backed up por dados experimentais?" This case is the answer in numbers rather than in an opinion.

WHAT IT DOES. Sixteen 'propertyPoint' operations, one per MEASURED state of the nitrogen + hydrogen binary, at exactly the (T, P, x) the experimenters reported. The engine computes the molar volume with the SAME declaration the green ammonia plant carries – SRK, van der Waals one-fluid, kij = 0 – and prints it. The measurement sits beside it in 'constant/experiments/N2-H2-density-jced-7b00694.dat', cited to its primary publication.

HOW TO READ THE ANSWER. Each operation reports 'v_molar' in m3/mol. The mass density the experimenters measured is

rho = MW_mix / v_molar , MW_mix = x∗MW(N2) + (1-x)∗MW(H2)

and the two molar masses are in the components' own records (28.013 and 2.016 kg/kmol). Do that division for the four points at x(N2) = 0.50008 and 250 K and you have SRK's error climbing with pressure, which is the whole lesson: a cubic equation of state fitted to critical constants is a correlation, and 200 bar is far outside where its two parameters were determined.

'bin/curate/check_srk_h2n2_aad.py' does exactly that arithmetic, from THIS run's own output and THIS case's own evidence file, and refuses if either moves. The number is not written down anywhere – it is recomputed, because a transcribed agreement statistic is a second home for a fact the run owns.

WHAT THIS CASE DOES NOT SAY. It does not say SRK is wrong, and it does not say a better model exists in this tree – none does for this binary today. It does not test the loop's COMPOSITION: see the caveat in the evidence file's own header. And it says nothing about ammonia, which is the strongly associating component the loop actually has to condense.

The green ammonia plant in tutorials/plant/greenAmmoniaPEQ_baseCase runs its synthesis loop at around 200 bar and condenses its product near 250 K, and it prices every stream with a Soave–Redlich–Kwong equation of state whose only inputs are each component's critical temperature, critical pressure and acentric factor. Two questions follow, and only the second one has an answer a student can check:

1. Is that reasonable? — an engineering judgement. 2. How far from measurement is it? — a number.

Sixteen propertyPoint operations, one per measured state of the nitrogen + hydrogen binary, at exactly the temperature, pressure and composition the experimenters reported. The engine computes the molar volume with the plant's own declaration — SRK, van der Waals one-fluid mixing, and kij = 0, which the run announces rather than assuming in silence:

The measurement sits beside it in constant/experiments/, cited to its primary publication:

R. Hern?ndez-G?mez, D. Tuma, A. G?mez-Hern?ndez, C. R. Chamorro, ∗Accurate Experimental (p, ?, T) Data for the Introduction of Hydrogen into the Natural Gas Grid: Thermodynamic Characterization of the Nitrogen–Hydrogen Binary System from 240 to 350 K and Pressures up to 20 MPa∗, J. Chem. Eng. Data (2017). [doi:10.1021/acs.jced.7b00694](https://doi.org/10.1021/acs.jced.7b00694)

Each operation reports v_molar in m^3/mol. Turn it into a mass density with

powder

compaction01_mcc

tutorials/props/powder/compaction01_mcc

mcc_inDie	mcc_inDie_highWindow	mcc_lubricated
compactionFit	compactionFit	compactionFit

What it does: Microcrystalline cellulose on the compaction bench: Heckel, Kawakita and Ryshkewitch-Duckworth fitted to two open datasets, in die and out of die, with the declared Heckel window shown to move Py

The story: compaction01 – MICROCRYSTALLINE CELLULOSE ON THE COMPACTION BENCH.

MCC is the main excipient of the apalutamide tablet case (tutorials/batch/plant/apalutamide01_tablets: MCC 295.5 + silicified MCC 116.9 mg of a 700 mg core). This case fits the three compaction models to OPEN measurements of MCC, so the numbers a tablet-press design needs – how hard the press must push, how much the bed shrinks, how strong the tablet comes out – have a source a reader can open.

WHY A NEW FOLDER, 'tutorials/props/powder/'. The tutorial folders of 'props/' are named by the subject a student studies, and powder compaction is none of the existing ones (it is not thermodynamics, transport or a membrane): it is solids processing, the first props bench of its kind.

THREE OPERATIONS, TWO SOURCES (both CC BY 4.0; datasets in constant/experimental/, each with its own provenance header):

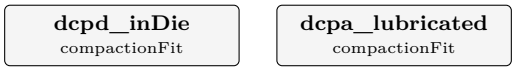
mcc_inDie Avicel PH200, van der Haven et al., Sci. Data 13 (2026) 1468 – 45 tablets compressed once on a compaction simulator, IN-DIE density at maximum force; 22 tablets crushed diametrally. Heckel on the declared low-pressure window, Kawakita on all pressures, Ryshkewitch-Duckworth on the crushing data, compared with the sigma_0 and k_b the dataset itself reports. mcc_inDie_highWindow the SAME 45 tablets, Heckel on a high-pressure window: the mean yield pressure roughly doubles. The window IS part of the answer, which is why the case declares it and the op never chooses it. mcc_lubricated CEOLUS UF-711 + 2 % sodium stearyl fumarate + 0.3 % silica (Kukuls & Mohylyuk 2025 dataset; protocol of Mohylyuk et al., Pharmaceutics 16 (2024) 362), the mean of ten tablets at each of six pressures, OUT OF DIE, compared with the Py = 106 MPa that paper reports.

WHAT TO READ IN THE OUTPUT. Py of MCC is low (tens to ~100 MPa in die on the low-pressure line): it deforms PLASTICALLY, which is why it binds so well and why it is the filler of choice for direct compression. Compare it with compaction02 (dicalcium phosphate, brittle, several hundred MPa). The out-of-die Py is HIGHER than the in-die one on similar pressures because the ejected tablet has recovered the elastic part of its strain.

THE PAPER'S Py IS NOT REPRODUCED, AND THE REASON IS THE LESSON. Mohylyuk et al. 2024 state their linear region as 100-150 MPa. The deposited data carries ONE of its six pressures in that window (137 MPa), and a line through fewer than 4 points refuses here, so this case declares 90-340 MPa (4 points) and gets a different, larger, Py. (The two-point slope between the 91 and 137 MPa rows would give about 100 MPa – close to the paper's – but a two-point line has no residual to judge it by.) Both numbers are printed; nothing is tuned.

A FINDING, PRINTED AND NOT TUNED: on both materials of the van der Haven dataset (here and in the other powder case) the fitted k_b agrees with the dataset's own constant within 10 %, but the fitted sigma_0 comes out about 1.5 times the dataset's. A fit in sigma_t instead of ln(sigma_t) does not close it (measured: 30.9 and 28.4 MPa). The files read do not say how the dataset's "Eq. 4" was fitted or on which porosity; its report PDF was not read. sigma_0 is an extrapolation to zero porosity, so a small difference in slope or in the porosity basis moves it a lot.

HOW TO USE THIS FOR YOUR FORMULATION. 1. Find an OPEN dataset (CC BY: MDPI Pharmaceutics, Int. J. Pharm. X, Sci. Data, Zenodo, institutional dataverses) for the excipient that dominates your blend – the same grade if you can. Check its licence on the article page; NonCommercial or "available on request" is not usable. 2. Write its rows in the experiments grammar (copy one of the files in constant/experimental/): P in MPa and ONE of D, porosity or the compact's density (then declare 'trueDensity', with its source). Say whether the density is in-die or out-of-die. 3. Plot the Heckel line first (run with a wide window and look at the 'heckel' table's residuals), then DECLARE the linear region you defend, with a 'reason'. Report Py WITH its window and its in-die or out-of-die basis; a Py without them cannot be compared. 4. If the source reports its own values, put them in 'reported {}'. A difference is a finding



(window, density basis, true density), never something to tune away. LIMITS, said plainly: these are data for MCC, not for your blend. NO mixture rule (for Py, sigma_0 or k_b) is implemented; the source's own ternary data shows mixtures do not follow a simple average. Lubricant (magnesium stearate) weakens MCC tablets and the lubricated dataset here is the closer stand-in for a real formulation. For another MCC grade the literature gives in-die Py = 52.2 +/- 4.2 MPa for Vivapur 102 at 11.28 mm (Lura et al., Int. J. Pharm. X 2 (2020) 100061, Table 2, CC BY) – quoted for comparison, not fitted here.

compaction02_dcpd_brittle

tutorials/props/powder/compaction02_dcpd_brittle

What it does: A brittle excipient on the compaction bench: dicalcium phosphate fitted to two open datasets (no open lactose dataset was found, and none is invented), against MCC's plastic behaviour in compaction01

The story: compaction02 – A BRITTLE EXCIPIENT ON THE COMPACTION BENCH: DICALCIUM PHOSPHATE, AND WHY IT IS NOT LACTOSE.

The donepezil tablet case (tutorials/batch/plant/donepezil01_tablets) is 62 % lactose monohydrate, a FRAGMENTING excipient. This case was meant to fit the compaction models to open lactose data, and it does not, because NO open dataset with tabulated lactose pressure-density or strength-porosity rows was found on 2026-11-02 (CC BY sources searched: MDPI Pharmaceutics, Int. J. Pharm. X, PMC open access, Zenodo, Data in Brief; the lactose datasets located were NonCommercial, figure-only, or "available on request"). No lactose numbers were invented in its place.

What it fits instead is the open brittle reference that WAS found, from the same two sources as compaction01, so the plastic-against-brittle contrast can be read off two cases built the same way:

dcpd_inDie DCPD Emcompress premium (dihydrate), van der Haven et al., Sci. Data 13 (2026) 1468, CC BY 4.0: 42 tablets, in-die density at maximum force; 19 crushed diametrally. Compared with the sigma_0 and k_b the dataset itself reports. dcpa_lubricated CaHPO4 anhydrous DI-CAFOS A60 + 2 % sodium stearyl fumarate + 0.3 % silica (Kukuls & Mohylyuk 2025, CC BY 4.0; protocol of Mohylyuk et al., Pharmaceutics 16 (2024) 362), out of die, compared with that paper's Py = 434 MPa.

WHAT TO READ. Py here is several hundred MPa – several times MCC's (compaction01) – the signature of a material that densifies by FRACTURE, not by flow. Its tablets are weak at a given porosity (low tensile strength) and k_b is large: the strength collapses fast as the pores open. Lactose sits between the two: for Tablettose 80 the literature gives an in-die Py of 120.8 +/- 1.5 MPa at 11.28 mm, against 52.2 +/- 4.2 MPa for MCC Vivapur 102 in the same study (Lura et al., Int. J. Pharm. X 2 (2020) 100061, Table 2, CC BY) – quoted for the donepezil group to compare with, NOT fitted here, because the study gives the curves only as figures.

A FINDING, PRINTED AND NOT TUNED: on both materials of the van der Haven dataset (here and in the other powder case) the fitted k_b agrees with the dataset's own constant within 10 %, but the fitted sigma_0 comes out about 1.5 times the dataset's. A fit in sigma_t instead of ln(sigma_t) does not close it (measured: 30.9 and 28.4 MPa). The files read do not say how the dataset's "Eq. 4" was fitted or on which porosity; its report PDF was not read. sigma_0 is an extrapolation to zero porosity, so a small difference in slope or in the porosity basis moves it a lot.

FOR THE DONEPEZIL GROUP. To fit your own lactose: find an open dataset (or digitise a CC BY figure, stating the reading error in the dataset header), write it in the grammar of the files in constant/experimental/, declare its Heckel window with a reason, and put the paper's own Py in ‘reported {}‘. Say which lactose (monohydrate milled, sieved, agglomerated, spray-dried, anhydrous): Py differs between grades by a factor of two. A wet-granulated blend (your case's route) compacts differently again from the dry excipient, and NO mixture rule is implemented – the excipient stands in for the blend, and you say so.

THE PAPER'S Py AND THIS CASE'S. Mohylyuk et al. 2024 analyse the F 0-100 formulation between 250 and 450 MPa. The deposited averages have three rows there (243 MPa falls just below it); a 3-point line refuses here, so the case declares 140-440 MPa (four rows) and both values are printed.

reactor

The theory you need. Three idealised steady reactors. Conversion reactor: stoichiometry only, $n_{\text{out}} = n_{\text{in}} + \nu\,\xi$, duty from the ONE enthalpy base $\Delta H_{\text{rxn}}(T) = \sum_i \nu_i h_i(T)$ (formation datum – no separate "heat of reaction" input, and any dict override is cross-checked aloud). CSTR: outlet at reactor conditions with rate $r(c_{\text{out}}, T)$, so $F\,(c_{\text{in}} - c_{\text{out}}) = r\,V$. PFR: the same rate integrated along the volume, $\mathrm{d}F_i/\mathrm{d}V = \nu_i\,r$. Arrhenius kinetics $k = A\,T^b e^{-E_a/RT}$, orders from the dict, reverse rates from the equilibrium constant (thermo-consistent by construction). Expect: CSTR conversion below PFR at equal volume (back-mixing), exponential T sensitivity, and equilibrium limits the kinetics can approach but never cross. *Full derivation: Theory Guide, the reaction-engineering chapter.*

thiele01_sphere_first_order

tutorials/props/reactor/thiele01_sphere_first_order

What it does: Single catalyst pellet: intraparticle concentration field, effectiveness factor, and the eta(phi) family, each verified against the first-order isothermal closed form

The story: One thielePellet operation.

THE RATE CONSTANT IS DECLARED HERE, and not on the catalyst record, because kinetics are equipment- and reaction-specific: the asset carries the SOLID, never the chemistry run on it. Two reactors loaded with the same catalyst would otherwise carry two copies of one rate constant and drift apart.

k = 40 1/s is a TEACHING VALUE chosen so the generalised modulus lands near 1 – the transition region, where the field has a visible gradient and eta is neither ~1 nor ~1/phi. It is not measured and is not claimed to be.

Solves the intraparticle boundary-value problem for one porous catalyst pellet, publishes the concentration field, the effectiveness factor and the Thiele modulus, and checks every one of them against the closed form.

With xi the normalised coordinate from the pellet centre (0) to its external surface (1) and u = c/c_s:

Both moduli are published because both conventions are in circulation and they differ by a factor of three for a sphere. The engine's own announcement in src/unitOperations/reactor/CatalystPellet.H uses the generalised one.

The equation is discretised with second-order central differences and handed to the existing solver::newtonND (finite-difference Jacobian, LU with partial pivoting) — no new dependency, no new solver, every step readable in src/unitOperations/reactor/pellet/PelletDiffusion.cpp.

xi is one column, not two aliases: it is r/R for a sphere or a cylinder and x/L for a slab.

First-order isothermal is the rare case that has a closed form in all three geometries, so the numerical answer is not merely produced — it is checked:

thiele02_prater_temperature

tutorials/props/reactor/thiele02_prater_temperature

What it does: Single catalyst pellet: intraparticle concentration field, effectiveness factor, and the eta(phi) family, each verified against the first-order isothermal closed form

The story: One thielePellet operation.

THE RATE CONSTANT IS DECLARED HERE, and not on the catalyst record, because kinetics are equipment- and reaction-specific: the asset carries the SOLID, never the chemistry run on it. Two reactors loaded with the same catalyst would otherwise carry two copies of one rate constant and drift apart.

k = 40 1/s is a TEACHING VALUE chosen so the generalised modulus lands near 1 – the transition region, where the field has a visible gradient and eta is neither ~1 nor ~1/phi. It is not measured and is not claimed to be.

The SAME pellet as thiele01_sphere_first_order, with one block added, so the difference between the two runs is the temperature.

Everything else — catalyst, species, T, P, rate constant, diffusion, grid, verification tolerances — is thiele01 unchanged. Run both and diff the output: nothing else moves.

The reaction is exothermic, so the pellet is hottest where the reactant is most depleted, which is the centre:

The field CSV gains two columns, T_over_Ts and T_K, one value per node — so the temperature is a FIELD, not a headline number, and the EduTool paints the same discs by it.

The species and energy balances inside a pellet carry the same reaction term. Eliminate it between them and, for constant D_eff and k_eff and any kinetics at all, what is left is a first integral — Prater's relation:

So the temperature field costs no second boundary-value problem. It is algebra over the concentration field the operation already solved.

reconciliation

reconcile01_recycle_loop

tutorials/props/reconciliation/reconcile01_recycle_loop

What it does: Seven flow meters on an invented recycle loop, reconciled under four node balances: the residuals of the raw readings, the weighted least squares that is also the Bayesian posterior mode, the chi-square and measurement tests that catch a meter planted to read 15 t/h high, and a prior from yesterday – the witness of the EduTool on data reconciliation

The story: reconcile01 – SEVEN METERS THAT DO NOT CLOSE FOUR BALANCES (DEV.md 4c C121).

An invented recycle loop (constant/plant/network: a mixer, a reactor, a separator and a purge splitter, seven streams, one flow meter on each) read once (constant/plant/readings). The readings carry noise, so not one node balance closes; the residuals are of the size the meters' own sigmas predict. The witness of the EduTool "Data reconciliation, and how Bayes helps", which runs this case in the browser.

WHAT IS SYNTHETIC, said plainly. The plant, its true flows, the meter sigmas, the noise, the planted gross error and yesterday's prior are all invented. Nothing here is a measurement of anything. The point is the method, and an invented plant lets the page show the TRUTH beside the readings and the reconciled flows – which no real plant can.

THE FOUR OPERATIONS, one per question the page asks.

honest the readings as they are. Weighted least squares under the four balances: the posterior mode for Gaussian meters and a flat prior. The objective is small against chi-square(4), and no meter's test exceeds the critical value.

drifted the same snapshot with F3 planted to read 15 t/h high (syntheticDrift). The global test rejects, the measurement test points at F3, and the reconciled flows show the error SMEARED over F3's neighbours.

driftedWithout the drifted snapshot with F3's meter taken out of service (exclude). The balances are projected onto the six remaining meters (the reactor and the separator merge into one envelope), the tests pass again, and F3 is read back from the balances – with how far the excluded meter sits from it.

yesterday the honest readings with a prior per flow from yesterday's reconciled values (constant/plant/yesterday): each reading and its prior combine by precision weighting, exactly, before the same reconciliation; the reconciled sigmas shrink again.

The significance level is DECLARED (alpha 0.05), never defaulted: the probability of a false alarm a plant accepts is a decision, not a constant.

safety

relief01_ammonia_loop_gas

tutorials/props/safety/relief01_ammonia_loop_gas

What it does: The ammonia synthesis loop's converter feed at the relieving pressure of a blocked outlet, at 150 bar and at 50 bar: the compressibility factor and Cp/Cv the gas relief-valve equation needs, computed with the SRK the loop runs on

The story: THE GAS SIDE OF A BLOCKED-OUTLET RELIEF VALVE ON THE AMMONIA SYNTHESIS LOOP (DEV.md 4c C61, the "Designing for overpressure" EduTool).

THE QUESTION. The converter's outlet is blocked while the recycle compressor goes on delivering the converter feed. The relief valve on the feed side must pass that whole flow at the relieving pressure, and the gas relief equation needs two properties of the gas there besides its molar mass: the compressibility factor Z and the ratio of specific heats k = Cp/Cv. This case computes both, for the same loop at 150 bar and at 50 bar – the two green-ammonia feasibility cases the Process-safety EduTool compares (tutorials/plant/greenAmmonia02_feasibility150bar and greenAmmonia02_feasibility50bar).

WHERE THE STATES COME FROM. composition – each plant's converged converter feed ('Preheated-Feed'), copied as the component flows in kmol/h exactly as the plant's converged/PreheatedFeed prints them. propertyPoint normalises the composition, so the flows ARE the composition; the EduTool reads them again as the relieving rate. gui/tests/overpressure.test.ts holds every number to the plant's own converged file. T – the same stream's temperature (653.15 K and 593.15 K): a blocked outlet relieves the gas as it arrives. P – the RELIEVING pressure, worked from the stream's operating pressure in the EduTool and written here to the digit: operating (gauge) = P_stream - 1.01325 bar design (gauge) = max(1.1 x operating, operating + 1.7 bar) (the Design Guide's rule of thumb for a PRELIMINARY design pressure, docs/designGuide.tex, "Pressure relief, flare & safety basics") MAWP (gauge) = design (gauge) – an ASSUMPTION, the lowest MAWP the vessel can have; a real MAWP is a property of the built vessel, never of a rule of thumb set pressure = MAWP (a single device) relieving (gauge) = max(1.10 x MAWP, MAWP + 3 psi) relieving (abs) = relieving (gauge) + 1.01325 bar The design pressure is a rule of thumb applied to a feasibility case that sizes no vessel, and the MAWP is assumed equal to it; no number here is the design pressure or the MAWP of any real loop.

WHAT IS COMPUTED. propertyPoint's base set: Z on the SRK vapour root, and gamma = Cp_ig/(Cp_ig - R) from the records' ideal-gas heat capacities – the ideal-gas ratio the gas relief equation is derived with.

The gas side of a blocked-outlet relief valve on the green-ammonia synthesis loop: the converter's outlet is shut while the recycle compressor goes on delivering the converter feed, so the valve on the feed side must pass that whole flow at the relieving pressure.

Two propertyPoint operations, one per loop pressure of the two C57 feasibility cases ([greenAmmonia02_feasibility150bar](../../../plant/greenAmmonia02_feasibility150bar) at 150 bar and [greenAmmonia02_feasibility50bar](../../../plant/greenAmmonia02_feasibility50bar)):

∗ the composition is each plant's converged converter feed (PreheatedFeed), copied as component flows in kmol/h — propertyPoint normalises it, and the EduTool reads the same numbers back as the relieving rate; ∗ the temperature is that stream's; ∗ the pressure is the relieving pressure of a single device set at an ASSUMED MAWP, taken equal to the preliminary design pressure the Design Guide's rule of thumb gives, max(1.1 × operating, operating + 1.7 bar), plus the 10 % accumulation — worked out in the propsDict header. A rule of thumb gives a preliminary design pressure, never a MAWP.

What the run gives the relief equation is Z (SRK vapour root, kij = 0, announced) and k = Cp/Cv (the ideal-gas ratio). The sizing itself is the EduTool's arithmetic: ∗Designing for overpressure∗ (DEV.md 4c C61), where the 50 bar loop turns out to need a relief valve about four and a half times larger than the 150 bar one in the sizing arithmetic, on the same declared blocked-outlet flow hypothesis — not a comparison of two real relief systems.

Nothing here is a design pressure or a relief load for a real loop.

relief02_acetone_fire_case

tutorials/props/safety/relief02_acetone_fire_case

What it does: An acetone drum in a pool fire: the boiling temperature at the relieving pressure, the latent heat there, and the vapour's Z and Cp/Cv – the fluid properties the fire-case relief load and the gas sizing equation need, computed by the engine rather than typed in

The story: THE FLUID SIDE OF A FIRE-CASE RELIEF VALVE (DEV.md 4c C61, the "Designing for overpressure" EduTool).

THE QUESTION. A drum of acetone, a flammable solvent, sits in a pool fire. Its relief valve opens at the set pressure and the pressure climbs to the relieving pressure P1 = set + allowed accumulation; there the liquid BOILS, and the fire's heat leaves as vapour. The relief load is the heat absorbed divided by the latent heat, and the valve passes that vapour. So four properties of the fluid decide the valve, and all four are computed here:

T_bubble the boiling temperature at P1 (the relieving temperature) Hvap_acetone the latent heat of vaporisation at that temperature Z the vapour's compressibility factor at (T, P1) gamma Cp/Cv of the vapour (the ideal-gas ratio, Cp_ig/(Cp_ig-R))

THE NUMBERS ARE AUTHOR-SET, and the EduTool moves them. P is the relieving pressure of a drum whose MAWP is 5 barg, protected for the fire case with the set pressure at the MAWP: 1.21 x 5 barg + 1.01325 bar = 7.06325 bar absolute. The 5 barg is a round number chosen for the lesson, not a property of any real drum. T is the boiling temperature the SAME run reports at that pressure (T_bubble), written back by hand so that Z, gamma and the latent heat are evaluated AT the relieving state; the EduTool does the same thing live, in two runs, whenever the reader moves the MAWP, and its test holds this file's T to its own T_bubble.

WHERE EACH NUMBER COMES FROM. T_bubble: the bubble point of pure acetone on the package in constant/thermoPhysPropDict (ideal liquid, SRK vapour). Hvap_acetone: the record's HvapTb carried to T by the Watson correlation, Component::Hvap_latent – the same term the engine subtracts from the ideal-gas enthalpy to price every liquid stream. Z: the SRK vapour root. gamma: the record's ideal-gas heat capacity.

WHY ACETONE AND NOT TOLUENE. The first draft of this case was a toluene drum, and its run announced that toluene's Antoine record is fitted only from 273 to 380 K – below the normal boiling point, so every boiling temperature of a pressurised toluene drum is an EXTRAPOLATED vapour pressure. A relief temperature resting on an extrapolation is a weak first lesson. Acetone's record covers 259.16 to 507.60 K, which holds the relieving state of any drum this EduTool lets the reader set.

WHAT THIS CASE DOES NOT SAY. Nothing here is a relief-valve design: the sizing is the EduTool's arithmetic on these numbers, and no number in either is a design for a real vessel.

The fluid side of a fire-case relief valve. A drum of acetone sits in a pool fire; its valve opens at the set pressure (here the MAWP, 5 barg — a round number for the lesson) and the pressure climbs to the relieving pressure with the 21 % fire accumulation, 7.06325 bar absolute. There the liquid boils, and the fire's heat leaves as vapour.

One propertyPoint operation, at the relieving pressure and at the boiling temperature the same run reports there, asks for the four numbers the relief load and the gas sizing equation need:

Hvap_<comp> is a property key added for this case (DEV.md 4c C61): it is the same latent heat the engine subtracts from the ideal-gas enthalpy to price every liquid, and it refuses at or above the critical temperature.

Why acetone and not toluene: toluene's Antoine record is fitted only from 273 to 380 K, below its own normal boiling point, so every boiling temperature of a pressurised toluene drum would be an extrapolated vapour pressure. Acetone's covers 259.16 to 507.60 K.

The sizing is the EduTool's arithmetic: ∗Designing for overpressure∗. Nothing here is a relief design for a real vessel.

scan

The theory you need. Property scans sweep a model across T, P or composition and plot what the thermodynamics DOES: $P^{\mathrm{sat}}(T)$ curves, $\gamma_{\pm}(m)$, VLE envelopes, ternary diagrams, phase boundaries. Nothing is fitted – these ops answer "how does the selected model behave?", the SEE step of the props loop (CREATE → SEE → TEST → FIT → PROMOTE). Expect model disagreements to be VISIBLE (overlay two methods and look), and every curve exportable as CSV next to the case. *Full derivation: Theory Guide, the Props Guide.*

binary01_lle_water_nbutanol

tutorials/props/scan/binary01_lle_water_nbutanol

What it does: Binary LLE g_mix + common-tangent (water/1-butanol) at 298.15 K via propertyScanBinary, cited Winkelman 2009 UNIQUAC

The story: Binary liquid-liquid teaching map – water / 1-butanol at 25 C.

The molar Gibbs energy of mixing g_mix(x1) swept across composition PLUS the two coexisting liquid compositions from ONE liquid-liquid IsothermalFlash (PhaseSet::LL). The two binodal points lie on the g_mix curve and share its common tangent – the student reads the split straight off the diagram.

gamma comes from the CITED Winkelman et al. (2009) UNIQUAC LLE set (Table 2; structural r,q from Table 1), so the g_mix curve goes NON-CONVEX and the flash emits the real water/1-butanol binodal: ~1.9 mol% butanol in the water-rich phase and ~49 mol% butanol in the butanol-rich phase (matching their Figs 1-2 at 298 K). See README.md.

The flash feed is set to z(water) = 0.80 (20 mol% butanol), INSIDE the asymmetric gap; an equimolar feed would lie outside it (both binodal branches sit below 50 mol% butanol). Run-only smoke (the CSV is a teaching curve, not pinned KPIs).

Water + 1-butanol (n-butanol) is ∗the∗ classic partially-miscible binary. At 25 °C it splits into a water-rich liquid (~2 mol % butanol) and a butanol-rich liquid (~50 mol % butanol). A g_mix(x_water) scan should therefore show a clearly non-convex region: two binodal points sharing a common tangent, which a student reads the split straight off.

and binaryLle.csv is a g_mix(x1) curve that goes non-convex, plus the two binodal points the liquid-liquid flash locates on it:

The agreement is essentially exact: the cited UNIQUAC fit reproduces the published mutual solubilities.

- J.G.M. Winkelman, G.N. Kraai, H.J. Heeres, ∗"Binary, ternary and quaternary liquid-liquid equilibria in 1-butanol, oleic acid, water and n-heptane mixtures"∗, Fluid Phase Equilibria 284 (2009) 71–79, doi:10.1016/j.fluid.2009.06.013.

- Interaction parameters — their Table 2 (p.73), binary 1-butanol(1)/water(3), valid 273–363 K, with the quadratic temperature correlation $A_{ij}(T) = a + b\cdot T + c\cdot T^2$ (Eq. 10), $\tau_{ij} = \exp(-A_{ij}/T)$ (Eq. 7): - A_1,3 (butanol→water): a = 155.31, b = 1.0822, 10?·c = -43.711 - A_3,1 (water→butanol): a = -579.36, b = 2.7517, 10?·c = -6.7700 - Structural r, q — their Table 1 (p.72): 1-butanol r = 3.9243, q = 3.668; water r = 0.9200, q = 1.400.

The numbers are inline here, fully provenanced above; the record is STAGED CASE-LOCALLY, not curated: it lives at tutorials/steady/flash/marcilla02_lls_ternary_invariant/constant/parameters/UNIQUAC/nButanol-water.dat with reviewStatus interim, and promotion into data/standards/ is the maintainer's batch review. This README used to claim the numbers already lived under data/standards/ – asserting a curation status that had been deliberately withheld, which is a worse error than saying nothing.

What to expect (golden-locked):

kind	unit/stream	key	expected
diag	lle	T	298.15
diag	lle	split	1

hxy01_ethanol_water_1atm

tutorials/props/scan/hxy01_ethanol_water_1atm

What it does: Enthalpy-concentration locus (h-x-y) of ethanol/water at 1 atm on the elements datum – the data a Ponchon-Savarit construction is drawn on

The story: The enthalpy-concentration locus of ethanol/water at 1 atm.

McCabe-Thiele carries equilibrium and material balance under CONSTANT MOLAR OVERFLOW – one mole condensing releases exactly what one mole vaporising absorbs, whatever the composition. This case publishes the quantity that assumption is about: the saturated-liquid enthalpy h(x) on its bubble line, the saturated-vapour enthalpy H(y) on its dew line, and the equilibrium tie between them, all on Choupo's ONE enthalpy datum (the elements at 298.15 K).

lambda(x) = H(y∗) - h(x) is the molar heat of vaporisation ALONG the locus. CMO says it is a constant. Read the two lambda diagnostics and decide for yourself.

Run-only + KPI golden; see README.md for the provenance of every number and for what is NOT validated.

The saturated-liquid enthalpy on its bubble line, the saturated-vapour enthalpy on its dew line, and the equilibrium tie between them — the data an enthalpy-concentration (Ponchon–Savarit) construction is drawn on, and the first thing the engine publishes that carries enthalpy against composition.

enthalpyConcentration.csv — a regular table, one header, homogeneous rows:

Every row is one equilibrium. It carries ∗both∗ ends of a tie line — the liquid (x1, h_liquid) and the vapour (y1, H_vapour) that are in equilibrium with each other — at the one temperature T_K they share. So nothing downstream pairs rows by index and nothing interpolates one end of a tie. role says only which composition was the uniform grid node:

The saturated-liquid curve is (x1, h_liquid) over all rows; the saturated-vapour curve is (y1, H_vapour) over all rows. status is ok or names a refusal; a refused node keeps its grid coordinate and leaves the solved fields empty, so a gap is visible rather than silently bridged.

enthalpyConcentration.meta — a key,value sidecar, written on every run. It states the two components, the pressure, which enthalpy datum the two columns are on, which kernel computed each, the tie contract, whether the heat of mixing is included, and the reason for every refused node. The construction's lever arms are enthalpy ∗differences∗, so a constant offset cancels in the geometry — which is exactly why the file has to say what its axis means instead of letting the next reader assume.

Both enthalpy columns are absolute on Choupo's one enthalpy base, the elements at 298.15 K, from the same two kernels every energy balance and duty in the engine is priced on:

scan2d01_co2_compressibility

tutorials/props/scan/scan2d01_co2_compressibility

What it does: Z(T,P) for CO2 on Peng-Robinson over a 15 x 20 grid that crosses the critical point: the compressibility surface, one row per node

The story: THE COMPRESSIBILITY SURFACE, NOT A CURVE.

'propertyScan2D' sweeps TWO state variables over a rectangle and reports the property at every node – long-form CSV, one row per (T, P), ready to pivot into a heat map. Here it is Z(T, P) for CO2 on Peng-Robinson, 280-420 K by 1-200 bar: a 15 x 20 grid that walks straight over the critical point (304.13 K, 73.77 bar).

What to read: along an isotherm below Tc the surface DROPS steeply and then turns up – the liquid-like branch; above Tc the same isotherm is smooth: the discontinuity is a coexistence line, and the grid crosses where it ends; Z $\rightarrow$ 1 in the whole low-P edge, which is the ideal-gas limit falling out of a cubic rather than being assumed.

The op reports 'failures' – nodes where the property could not be evaluated – as a diagnostic, so a grid that quietly returned fewer points than it promised is visible in the payload rather than only in the CSV's line count. The expected file pins it at zero: on this rectangle every node must solve.

Why the case exists: 'propertyScan2D' had NO case and no gate, though 'propertyScan1D', 'propertyScanBinary' and 'propertyScanTernary' all have one. Its sibling vaporPressureFit was in the same position, and writing the first case for THAT one segfaulted choupoProps twice.

ternary01_audit_vlle

tutorials/props/scan/ternary01_audit_vlle

What it does: Ternary VLLE phase map (compA/compB/compC) at 350 K, 1 bar via propertyScanTernary

The story: ILLUSTRATIVE / SYNTHETIC DATA. compA / compB / compC are NOT real species: they are artificial components (case-local constant/components/ + inline NRTL pairs in thermoPhysPropDict) deliberately tuned to guarantee a ternary VLLE region, so this case exercises the propertyScanTernary classifier on a known-3-phase map. Architecture (see thermoPhysPropDict): A and B mutually immiscible (LL gap on the A-B axis), C a volatile bridge soluble in both liquids. At 350 K, 1 bar the equimolar feed gives vapour rich in C, L_alpha rich in A, L_beta rich in B.

Expected map (14 intervals/edge, 78 nodes): VLLE 36, LL 29, VL 0, 1-phase 13, 22 tie-lines, 0 failures. The point to SEE: a healthy spread of 3-phase (VLLE) and LL nodes with zero solver failures — the classifier resolves the engineered gap node-by-node.

What to expect (golden-locked):

kind	unit/stream	key	expected

solvents

solvent01_synthetic_mixture

tutorials/props/solvents/solvent01_synthetic_mixture

What it does: DIDACTIC EXAMPLE WITH SYNTHETIC PARAMETERS: two fictitious solvents A and B, a fictitious polymer P between them – the Hansen distance along the A/B line has its minimum at 50:50 by volume, hand-checkable

The story: solvent01 – DIDACTIC EXAMPLE WITH SYNTHETIC PARAMETERS (DEV.md 4c C128, adjustment 2: start with a synthetic case, then a real one, then the confrontation with measurements).

THE ARITHMETIC, by hand (MPa^0.5):

solventA dD 16 dP 2 dH 4 solventB dD 16 dP 10 dH 12 polymerP dD 17 dP 6 dH 8 R0 4

Along the A/B line at volume fraction s of B the mixture rule gives (16, 2 + 8 s, 4 + 8 s), so

Ra^2 = 4 (16 - 17)^2 + (8 s - 4)^2 + (8 s - 4)^2 = 4 + 2 (8 s - 4)^2

which is 36 at either pure end (Ra = 6.000, RED = 1.5) and 4 at s = 0.5 (Ra = 2.000, RED = 0.5): the minimum sits at 50:50 BY CONSTRUCTION, and the dispersion offset of 1 keeps it from being a degenerate zero. The two solvents have equal Vliq, so the volume, mole and mass bases coincide here – the basis conversion is exercised on the real case instead.

THE PHASE WORD IS ‘notVerified‘, honestly: the package declares an ideal liquid (gamma = 1), which has no excess Gibbs energy and can never demix, so a stability test on it would say "homogeneous" about every pair ever asked. The op marks every blend point rather than claim a verification the model cannot give.

Two fictitious solvents A and B and a fictitious polymer P between them, so the Hansen distance along the A/B line has its minimum at 50:50 by volume — by construction, and checkable by hand. Nothing here is a real substance; the engine says so on every run ([synthetic] component 'solventA' is NOT a real substance), and the records carry provenance { source synthetic; }.

All values in MPa^0.5 (the records store Pa^0.5, 1000 times larger):

Hansen's distance, with the factor 4 on the dispersion term (his 1967 thesis, Eq. 8.2), along the line at volume fraction s of B:

so Ra = 6.000 at either pure end (RED = 1.5, outside the sphere) and Ra = 2.000 at s = 0.5 (RED = 0.5, inside). The dispersion offset of 1 keeps the minimum from being a degenerate zero. The two solvents have the same molar volume, so the volume, mole and mass bases coincide here; the conversion is exercised on the real case (solvent02).

The package declares an ideal liquid, and gamma = 1 has no excess Gibbs energy: it can never demix, so a stability test on it would say "one liquid" about every pair ever asked. The op marks every blend point notVerified rather than claim a verification the model cannot give — the honest third outcome of the phase check (the other two, homogeneous and twoPhase, are live on solvent02 under UNIFAC). The pure ends carry pure: one component, nothing to split.

∗ the mixture rule is the volume-fraction average of each parameter — an approximation (no excess volume; each solvent keeps its own split); ∗ the parameters are held constant at their reference temperature (Tref 298.15 K on every record); no correction exists in the engine, and the declared T decides the phase check alone; ∗ Ra is an affinity, not a solubility: no saturation concentration is published.

What to expect (golden-locked):

solvent02_polystyrene_hexane_blends

tutorials/props/solvents/solvent02_polystyrene_hexane_blends

What it does: Polystyrene (Hansen 1967, solute G) against two hexane blends: hexane + acetone, two solvents each short of the polymer that meet it between them, and hexane + nitromethane, whose blend the mixture rule likes exactly where UNIFAC finds two liquids

The story: solvent02 – THE REAL CASE (DEV.md 4c C128, adjustment 2, step two).

The target is polystyrene as Hansen placed it in his 1967 thesis (solute G, Table 4.1: centre (8.6, 3.0, 2.0) (cal/cm3)^0.5, radius 3.5); the solvents are three of his Table 2.1 placements, read from the page images and converted to Pa^0.5 in constant/components/*.dat, one citation per value. Two blends, two lessons:

1. hexane + acetone, by VOLUME. In the engine's MPa^0.5 (the thesis's (cal/cm3)^0.5 times 2.0455) polystyrene's radius is R0 = 7.159; pure hexane lies outside the sphere (Ra 9.238, RED 1.290) and pure acetone just inside its edge (Ra 6.638, RED 0.927 – and rated 3, "strongly swollen, slight solubility", in the thesis's own test, Table 2.3). The blend dips well inside: the minimum is Ra 4.724 (RED 0.660) at 65 % acetone by volume, and 50:50 gives 4.992 (RED 0.697). The mixture rule lets two solvents on opposite sides of the target meet it between them, which is the observation Hansen checked his placements against (Section 2.5: "mixtures of non-solvents ... should ... dissolve the solute. This has always been found to be the case"). UNIFAC is asked whether the pair is one liquid at every point.

2. hexane + nitromethane, by MOLE (the basis conversion exercised: mole fractions become volume fractions through the records' Vliq, and the run prints both). Both ends are far outside the sphere (RED 1.290 and 1.850); the mixture rule puts the middle of the line inside (Ra 5.399, RED 0.754 at x = 0.6, which is 38 % nitromethane by volume). But hexane and nitromethane are an immiscible pair at 25 C, and the case's UNIFAC is asked: where the Michelsen test finds a second liquid the op REFUSES to represent the pair as one solvent – no averaged triple, no Ra, the point marked 'twoPhase' – and the minimum is taken over the points that survive. Measured: 17 of 19 blends (x = 0.05 to 0.85) are two-phase, every one where the rule would have put the blend inside the sphere among them, and the survivors all lie outside it – the minimum over survivors is pure hexane, RED 1.290. The averaged number would have been the best on the line, and it describes a solvent that does not exist. (A two-phase pair is not useless – it may serve an extraction; it is only not one solvent.)

T = 298.15 K is also every record's Tref, so no parameter is used away from the temperature it was placed at; the run says so either way.

The real case of the solvent-selection lesson (DEV.md 4c C128). The target is polystyrene as Hansen placed it in his 1967 thesis (solute G, Table 4.1: centre (8.6, 3.0, 2.0), radius 3.5 in (cal/cm^3)^0.5 — R0 = 7.159 MPa^0.5 in the engine's unit); the solvents are three of his Table 2.1 placements, transcribed from the page images into case-local overlay records (constant/components/.dat) with the thesis page and row beside each value, converted to Pa^0.5 by sqrt(4.184e6) = 2045.48, and marked interim. The reference temperature is adopted as 25 °C (the thesis prints none beside its tables); the run is at 25 °C so nothing is moved away from it.*

*Pure hexane lies outside the sphere and pure acetone just inside its edge (in the thesis's own test both were rated 3, "strongly swollen, slight solubility"); the blend dips well inside near 65 % acetone. That is the observation Hansen checked his placements against: *two non-solvents on opposite sides of a solute's sphere give a blend that dissolves it* (thesis, ?2.5, "this has always been found to be the case"). UNIFAC — the case's activity model, predictive from the records' groups — finds the pair one liquid at every point, so the word is homogeneous all along, which is what makes the blend a candidate at all.*

The composition is declared by MOLE, so the run converts it to volume fractions through the records' Vliq (54.1 cm^3/mol for nitromethane against 131.6 for hexane: equal moles is 29 % nitromethane by volume) and prints both. Both ends are far outside the sphere (RED 1.290 and 1.850), and the mixture rule puts the middle of the line inside it — on paper, a better blend than the first (Ra 5.399, RED 0.754 at x = 0.6).

But hexane and nitromethane are an immiscible pair at room temperature, and the case's UNIFAC says so: where Michelsen's tangent-plane test finds a second liquid the op refuses to represent the pair as one solvent — no averaged triple, no Ra, no RED for that point, the row marked twoPhase with its negative tm — and the minimum is taken over the points that survive. The averaged number would have been the best on

the line, and it describes a solvent that does not exist. A two-phase pair is not useless (it may serve an extraction); it is only not one solvent.

What UNIFAC answered, measured: 17 of the 19 blends are two-phase, from x = 0.05 to 0.85 (tm between -0.10 and -0.40), and only the two nitromethane-rich blends (x = 0.90 and 0.95) are one liquid — both outside the sphere (RED 1.340 and 1.572). Every composition where the mixture rule would have put the blend inside the sphere (roughly x = 0.3 to 0.8, RED down to 0.754) is refused, so the minimum over the points that survive is pure hexane, RED 1.290: no blend of these two is a solvent for polystyrene. The counts are pinned in expected (n_twoPhase, n_homogeneous).

This case also found an engine defect, fixed in the same slice. Its first run reported hexane + acetone two-phase at EVERY composition (tm down to -0.43), for a pair whose UNIFAC activity coefficients at 50:50 are 1.52 and 1.56 and which is miscible. The Michelsen tangent-plane distance in src/solver/StabilityTest.cpp omitted the ln $\gamma_i(y)$ term, so at the trivial point it read -G^E/RT instead of 0 and called every positive-deviation mixture unstable. With the term restored the pair is one liquid (tm at round-off) and the 38 corpus cases that reach the test kept every golden.

solvent03_polystyrene_observed

tutorials/props/solvents/solvent03_polystyrene_observed

What it does: Polystyrene (Hansen 1967, solute G) screened against thirteen pure solvents of the same thesis, beside the thesis's own dissolution ratings (Table 2.3) kept in constant/experimental/ – the confrontation of Ra and RED with what was observed

The story: solvent03 – THE CONFRONTATION WITH EXPERIMENT (DEV.md 4c C128, adjustment 2, step three).

No 'composition {}': the op SCREENS each declared solvent pure – one row each, Ra and RED against polystyrene's sphere (Hansen 1967, Table 4.1, solute G). Beside the run, constant/experimental/ hansen1967_table23_polystyrene.csv holds what the same thesis OBSERVED for each of these thirteen solvents (Table 2.3, column G, the 1-6 scale of page 20: 1 soluble ... 6 no visible effect), with the citation on every row. The op does not read that file: the prediction and the observation stay two tables, joined by the reader (the README does it by hand, the EduTool draws them side by side, the gate counts the agreement).

WHAT THE CONFRONTATION IS, said plainly. Hansen's sphere for this polymer was DRAWN THROUGH these very observations (Section 4.4: "the centers of the volumes of solubility ... have been determined" from the solvents that dissolve each solute), so agreement here shows that the transcription and the distance arithmetic reproduce his placement – it is a check of the method on its own training set, not an independent prediction. The thesis itself states the residual: about 2.5 % of the solvents beyond R0 + 0.5 dissolve, and about 2.5 % within R0 - 0.5 do not (page 39). Nitroethane (RED 1.39, rated 2 "almost soluble") and cyclohexane (RED 1.06, rated 1 "soluble") are that residual, in this set.

The package is 'ideal' because no mixture is asked for: every row is one pure solvent and the phase word is 'pure'.

The confrontation with experiment of the solvent-selection lesson (DEV.md 4c C128). No composition {}: the hansenMixture op screens each declared solvent PURE against polystyrene (Hansen 1967, solute G) — one row each, the phase word pure — and constant/experimental/hansen1967_table23_polystyrene.csv holds what the same thesis observed for each solvent (Table 2.3, column G, the 1–6 scale of its page 20: 1 soluble, 2 almost soluble, 3 strongly swollen with slight solubility, 4 swollen, 5 slight effect, 6 no visible effect), with the citation on every row. The op does not read that file; the two tables are joined here, by the EduTool, and by the gate.

Ra in MPa^0.5 against R0 = 7.159 (the thesis's 3.5 (cal/cm^3)^0.5); RED = Ra/R0.

Every solvent the thesis rated 6 lies outside the sphere; every solvent it rated 1 lies inside or — cyclohexane, RED 1.058 — within the ±0.5 (cal/cm^3)^0.5 band the thesis states for its own radii. The residual, read across the line RED = 1: nitroethane (RED 1.39, rated 2) and cyclohexane (RED 1.06, rated 1) dissolve from outside; acetone (RED 0.93, rated 3) does not quite from inside. Three of thirteen, where the thesis itself expects about one solvent in forty on each side beyond ±0.5 of the radius (page 39) — this set is small and its residual sits on the boundary, as the thesis says the deviations do.

Hansen's sphere for this polymer was drawn through these very observations (thesis ?4.4: the centres were determined from the solvents that dissolve each solute). Agreement here therefore shows that the transcription and the distance arithmetic reproduce his placement — a check of the method on its own training set, not an independent prediction of a solvent he never tried. No blend was dissolved by anyone: the thesis tabulates pure solvents only, and a measured point along a mixture line is what this corpus does not have.

The package is ideal because no mixture is asked for. Every parameter is a case-local overlay record with the thesis page and row beside the value, reviewStatus interim (transcribed from the page images, not the OCR text, whose columns are scrambled; a second reading pending).

expected pins each solvent's Ra_pure_<name> and the CSV cells of the screen; check_hansen_mixture rebuilds them from the records and prints the residual above as a measurement, failing only on a rated-6 solvent inside the sphere or a rated-1 solvent beyond the thesis's own band.

steam

The theory you need. Water/steam properties from IAPWS-IF97: regions (liquid, vapour, supercritical), $T_{\text{sat}}(P)$, and $h(T,P)/s(T,P)$ from the dimensionless Gibbs functions. Power cycles are enthalpy bookkeeping around them: pump work $\approx v\,\Delta P$, turbine work from isentropic expansion $\times$ efficiency, cycle efficiency $\eta = W_{\text{net}}/Q_{\text{in}}$ bounded by Carnot. *Full derivation: Theory Guide, the steam/power chapter.*

steam01_if97_verification

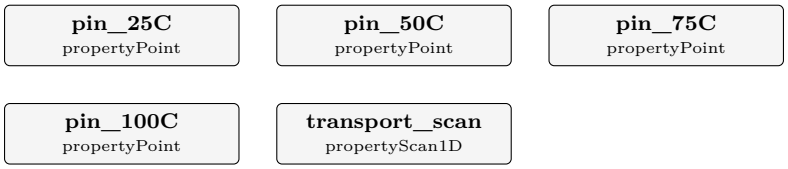
tutorials/props/steam/steam01_if97_verification

What it does: IAPWS-IF97 steam tables (R7-97(2012)) – the verification case. The six computer-program verification states of the release (Table 5 region 1, Table 15 region 2) evaluated as points, the saturation line 0.01-350 degC, and three isobars whose Tsat crossings pin the release's Table 36 backward values. The published numbers ARE the golden master (reltol 1e-8).

The story: the IAPWS-IF97 weapon case.

The release (IAPWS R7-97(2012)) publishes computer-program verification tables; this case evaluates EVERY one of them this slice covers and locks the published numbers as golden KPIs at reltol 1e-8 – a single wrong digit in a transcribed coefficient fails the regression:

Table 5 – region 1 at (300 K, 3 MPa), (300 K, 80 MPa), (500 K, 3 MPa) Table 15 – region 2 at (300 K, 3.5 kPa), (700 K, 3.5 kPa), (700 K, 30 MPa) Table 35 – psat at 300 / 500 K (the psat_MPa diag of the point ops) Table 36 – Tsat at 0.1 / 1 / 10 MPa (the Tsat_K diag of the isobars)



Plus the working artefacts: the saturated-steam table 0.01-350 degC (saturation.csv) and three isobars (h, s, v, cp vs T) crossing the saturation line – the crossing is ANNOUNCED in the log.

steam02_water_transport

tutorials/props/steam/steam02_water_transport

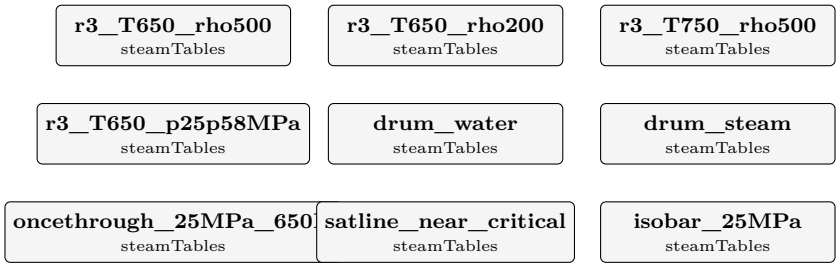
What it does: IAPWS water transport properties – viscosity (R12-08), thermal conductivity (R15-11) and surface tension (R1-76). Water flagged as a pure fluid (method IF97) routes the transport accessors to the matching IAPWS releases: the density comes from the IF97 thermodynamic kernel at the saturation state, fed to the (rho,T) transport kernels; surface tension is the R1-76 saturation-line form. A coarse 4-point scan (25/50/75/100 degC) pinned against the published IAPWS values, plus a fine sweep for the plot.

The story: the IAPWS water transport route.

Water flagged ‘pureFluids { water { method IF97; } }‘ routes the transport accessors to the matching IAPWS releases:

viscosity → R12-08 (industrial, critical enhancement off) thermal_conductivity → R15-11 (background, critical enhancement off) surface_tension → R1-76 (saturation line)

The (rho,T) viscosity / conductivity kernels get their density from the IF97 thermodynamic kernel at the SATURATION state (the legacy transport accessors carry no pressure, so p = p_sat(T) is the physical convention – saturated liquid / saturated vapour). Surface tension is a saturation-line property and takes only T.



‘pins‘ evaluates the three properties at 25/50/75/100 degC; the golden master locks them at reltol 1e-5 (the formulation is verified to 1e-8 by IAPWSTransport::verify(), which fires on every run). ‘scan‘ writes a fine sweep for the plot.

steam03_if97_region3

tutorials/props/steam/steam03_if97_region3

What it does: IAPWS-IF97 region 3 (near-critical and supercritical water, the Helmholtz form f(rho,T)). The three verification states printed in Wagner et al. 2000 Table A10 evaluated at (T, rho) as printed, one of them again from its printed pressure through the backward density, a 20 MPa drum boiler's water and steam on either side of the saturation line, a 25 MPa supercritical once-through point, the saturation line up to the critical point and a 25 MPa isobar crossing regions 1, 3 and 2.

The story: IAPWS-IF97 region 3, where the boiler drum and the supercritical once-through boiler live.

Region 3 is IF97's near-critical region: 623.15 K < T <= T_B23(p) and p_B23(T) < p <= 100 MPa. Its equation is a Helmholtz energy f(rho, T) (Wagner et al., J. Eng. Gas Turbines Power 122 (2000) 150-182, Eq. 25, 40 coefficients in Table A9), so the engine reaches it from (p, T) by solving p(rho, T) = p for the density on ONE branch of the isotherm – below Tc the liquid branch when p >= psat(T), the vapour branch below.

VALIDATED (the golden rows of the four Table A10 operations ARE the paper's printed values, not a recording, at reltol 1e-8 – the printed precision; the engine's own 1e-8 tripwire is IF97::verify(), which every steamTables run executes and which refuses the run above it): r3_T650_rho500, r3_T650_rho200, r3_T750_rho500 – Table A10 at the printed (T, rho): p, h, u, s, cp, w; r3_T650_p25p58MPa – the first state again, from its PRINTED pressure: the backward density must return rho = 500 kg/m3. NOT VALIDATED against any printed value (self-recorded goldens; they pin that the answer has not moved, never that it is right): drum_water / drum_steam – a 20 MPa drum boiler (Tsat = 638.9 K): water 4 K subcooled, steam 6 K superheated, both region 3; oncethrough_25MPa_650K – supercritical pressure, just below the pseudo-critical temperature, where cp peaks; satline_near_critical – the saturation line 600 K .. Tc: regions 1/2 on the line up to 623.15 K, region 3's two branches above it, h_fg falling to zero at Tc; isobar_25MPa – 600 .. 900 K: region 1, then region 3 (the cp peak), then region 2 above T_B23(25 MPa). IF97's own stated uncertainty against IAPWS-95 near the critical point is large (cp up to -53 % near 648 K and 22.3 MPa; the paper's Fig. 16b) – a near-critical cp from this case is the industrial formulation's number, not the scientific one.

thermo

The theory you need. Consistency tests interrogate DATA, not models: the van Ness point test checks measured (x, y, T, P) sets against the Gibbs–Duhem constraint (residuals in $\ln(\gamma_1/\gamma_2)$); Herington's area test is its integral cousin. A dataset that fails is not "bad" – the test says WHERE and HOW MUCH, and the fit that follows should weight accordingly. Expect plain-language verdicts with severity, not a pass/fail stamp. *Full derivation: Theory Guide, the consistency chapter of the Props Guide.*

bubble01_reaction_mass_boiling_point

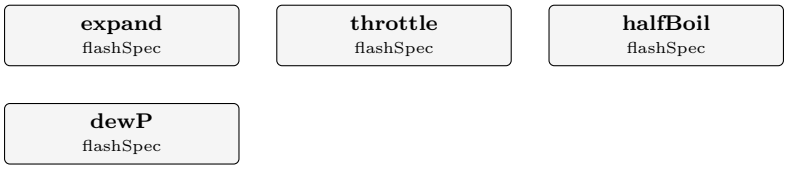
tutorials/props/thermo/bubble01_reaction_mass_boiling_point

What it does: The boiling point of a reaction mass: the bubble point of the cooling-failure batch's contents (fictitious A + B → P in solvent S, ideal), the technical limit (MTT) of the scenario

The story: the BOILING POINT OF A REACTION MASS, which is what the thermal-safety methodology takes as the technical limit MTT of an open vessel at atmospheric pressure.

The mass is the one in tutorials/batch/reactor/batch26_cooling_failure (and batch27/batch28, the same reaction dosed): the FICTITIOUS reactants A and B, their product P and the inert solvent S. constant/ is a COPY of batch26's sealed constant/ (the same four authored records under the same manifest, the same thermoPhysPropDict; only the reactor's own constant/reactions is left out, because no property operation reads it), so the boiling point below is computed on exactly the thermodynamics the reactor case declares: an IDEAL liquid (Raoult, gamma = 1) over an ideal gas, at the reactor's pressure, 1.013 bar.

The composition is the reactor's at batch26's shipped cooling failure (t_f = 600 s; mole fractions of the trajectory row at 600 s, 39.3 % of B converted). The process-safety EduTool rewrites the four lines with the reactor contents at the failure instant the reader chooses, read from the engine's own trajectory, and reads T_bubble back. ONE KEY PER LINE: the GUI's override anchors on a key at the start of a line, so a composition written on one line is a knob that silently misses.



WHAT THIS IS AND IS NOT. The mixture is ideal BY DEFINITION (the substances are fictitious and the case declares it so), so it has no azeotrope: its bubble point lies between the normal boiling points of the components present – here between B's (345.01 K) and P's (479.99 K), and much nearer the light end, because the volatile components dominate the vapour pressure. It is a bubble point at the failure instant: as a runaway converts the mass, its composition, and so its boiling point, moves – upward here, as the light reactants become the heavy product.

flashSpec01_wet_steam_expansion

tutorials/props/thermo/flashSpec01_wet_steam_expansion

What it does: The general flash specification (DEV.md 4c C214 W1): steam at 80 bar and 500 C expanded isentropically to 0.1 bar on IAPWS-IF97 ends WET (vapour fraction about 0.81, checkable against the steam table); a subcooled liquid throttled at constant enthalpy flashes; a vapour-fraction specification on a pure fluid lands on its saturation curve – the (P,S), (P,H), (P,V/F) and (T,V/F) pairs through one home

The story: A FLASH SPECIFIED BY A PAIR OTHER THAN (T, P) (DEV.md 4c C214 W1; docs/design/a-general-flash-specification.md).

A state of a fluid of known composition has two degrees of freedom. The isothermal flash fixes them as (T, P); a turbine knows its outlet PRESSURE and, ideally, its ENTROPY; a valve knows its pressure and its ENTHALPY; a condenser drum knows its pressure and how much of the stream is VAPOUR. Each op below asks one of those pairs of ONE home (flashState::specifiedFlash), and every answer is the state the isothermal flash publishes there – except a pure fluid ON its saturation curve, where no flash can decide the split and the saturated legs price it.

THE HAND CHECK (IAPWS-IF97 steam table, per kg): expand 80 bar, 500 C: s = 6.7262 kJ/(kg K), h = 3399.4 kJ/kg 0.1 bar saturated: Tsat = 45.81 C, s_f = 0.6492, s_g = 8.1501, h_f = 191.81, h_g = 2583.9 quality x = (6.7262 - 0.6492)/(8.1501 - 0.6492) = 0.8102 h_out = 191.81 + 0.8102 (2583.9 - 191.81) = 2129.8 kJ/kg isentropic work = 3399.4 - 2129.8 = 1269.6 kJ/kg throttle 10 bar, 450 K (subcooled liquid): h = 749.3 kJ/kg 1 bar saturated: h_f = 417.4, h_g = 2674.9 flash fraction x = (749.3 - 417.4)/(2674.9 - 417.4) = 0.147 halfBoil 1 atm, half vapour: T = Tsat(1 atm) = 373.124 K dewP 373.15 K, all vapour: P = Psat(100 C) = 101.418 kPa

WHAT THE STUDENT WATCHES. ‘expand‘ lands on the saturation PLATEAU: for a pure fluid T and P are one condition there, so the state’s coordinate is the vapour fraction, found by the lever rule on the saturated legs (no search). An isentropic search over a single-phase VAPOUR of fixed composition – what Choupo’s turbine does today – has no root here: below s_g at 0.1 bar no vapour carries that entropy (the vapour entropy jumps by the whole latent entropy at Tsat), so that search cannot land on this answer. That gap is what this op makes visible.

NOT MODELLED, said plainly: any non-equilibrium (a real turbine’s supersaturated "Wilson line" expansion is a kinetic effect); the irreversibility of a real expansion (the isentropic state is the ideal reference an efficiency is measured against). No number here is fitted: every value is an IF97 evaluation, a STRUCTURAL witness checkable by hand.

heavyWater01_isotope_effect

tutorials/props/thermo/heavyWater01_isotope_effect

What it does: Heavy water against ordinary water: the vapour-pressure isotope effect and the boiling points, from the records

The story: D2O against H2O, from the catalogue records.

WHAT THIS CASE EVALUATES. The saturation pressure of heavy water (record 'heavyWater': the Wagner equation of Herrig, Thol, Harvey & Lemmon, J. Phys. Chem. Ref. Data 47, 043102 (2018), Eq. (1)) and of ordinary water (IAPWS-IF97, via 'pureFluids') at 25/50/75/100 degC, and the normal boiling point of each pure liquid as its bubble temperature at 101325 Pa. Nothing here is stated from memory: bin/curate/check_heavy_water.py recomputes the heavy-water side from the IAPWS R16-17(2018) Helmholtz equation (Maxwell criterion), reads the ordinary-water side from the IF97 saturation equation, and holds this case's published numbers (CSV cells, pinned by 'csv' rows) to both.

WHAT IS VERIFIED. That the engine reproduces the primary equation: the Wagner arithmetic to 1e-6, the equation against the full D2O EOS to 8e-5, the boiling point of D2O against the EOS's. WHAT IS NOT. No measured datum is compared here; the ordinary-water side is IF97 (itself a correlation of IAPWS-95); 'Hvap' is the engine's Watson estimate from the record's Tc, Tb and HvapTb (exact at Tb, an extrapolation elsewhere – NOT the EOS latent heat). The record carries no formation datum, so 'propertyPoint' (which prints H_ig) refuses heavyWater by name: this case uses the scan operation, which evaluates only what it is asked for. No mixture property of D2O + H2O is claimed (the isotope-exchange equilibrium H2O + D2O = 2 HDO is not modelled).

phaseSplit01_freeze_water_ethanol

tutorials/props/thermo/phaseSplit01_freeze_water_ethanol

What it does: Freeze-concentration scan: a 10 mol% ethanol liquor cooled from 0 to -20 C, one SLE flash per kelvin – the ice point, the liquor concentrating along the freezing-point-depression identity

The story: THE PHASE SPLIT ALONG T (DEV.md 4c C118).

The same liquor flash21 freezes at ONE temperature (-15 C), cooled here from 0 to -20 C one kelvin at a time: at every grid point ONE isothermal flash, the flash21 unit's own solver (IsothermalFlash::solveCore), under flash21's own sealed records – water, ethanol, the curated NRTL pair, the C3 'phases (liquor liquid; ice solid crystallizing)' declaration. Nothing is re-derived; the point at 258.15 K IS flash21's answer (the gate holds it to flash21's golden).

WHAT A STUDENT WATCHES. Above the liquor's freezing point the feed is one liquid and the declared ice stays subsaturated: the water activity gamma_w x_w (0.917) sits BELOW the saturation value exp(-dG_fus/RT) the crystal would need (1 at the triple point, falling as T falls). Between -8 and -9 C the two cross, ice APPEARS (announced, between the two grid values it lies between), and from there down the liquor concentrates exactly along the freezing-point-depression identity

gamma_w ∗ x_w = exp(-dHfus (1 - T/Tt) / (R T))

with every quantity from the record's own data (Hfus 6008 J/mol, triple point 273.16 K) – published at every point as 'a_water' beside 'aEq_water', equal to round-off wherever ice is present, and recomputed independently by check_phase_split_scan. By -20 C nearly 60 % of the feed is ice and the liquor is about a quarter ethanol.

NOT MODELLED, said plainly (the run says it too): nucleation and supercooling – every point is the equilibrium ceiling; an ethanol solid or a eutectic – no record declares one, so the liquor never solidifies completely in this model; solute inclusion in the ice; the liquid/solid heat-capacity term of dG_fus (announced by the record, |T - Tt| up to 20 K here). Every sub-273 K vapour pressure is an announced extrapolation of the Antoine fit (it cancels in the SLE identity: both phases share one Psat), and the NRTL pair is used below its fitted window (announced). No number here is anchored to a measured freezing-point datum: a STRUCTURAL witness, like flash21.

What this witnesses (DEV.md 4c C118 stage 1, 2026-10-20): the phaseSplitScan props operation. At a FIXED overall composition (90/10 water/ethanol, moles) it sweeps temperature at fixed pressure and, at every grid point, solves the full phase split through the ONE flash home — IsothermalFlash::solveCore, the isothermalFlash unit's own solver, with the options the unit's own reader parses — under the case's own sealed records. The constant/ tree is flash21's, copied verbatim: the same water, the same ethanol, the same curated NRTL pair, the same C3 phases (liquor liquid; ice solid crystallizing) declaration. Nothing is re-derived, which is why the point at 258.15 K is flash21's answer (check_phase_split_scan arm (a) holds it to flash21's golden; its arms also hold single points on copies of flash16 and flash19 to those units' pH and V/F).

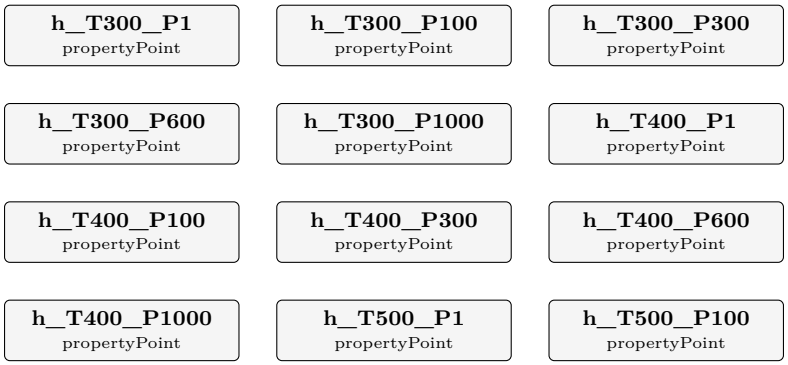
What a student watches. One isothermal flash per kelvin, 273.15 → 253.15 K:

Above the liquor's freezing point the feed is one liquid and the declared crystal stays subsaturated: the water activity γ_w·x_w (0.917) lies BELOW the saturation value exp(-ΔG_fus/RT) the crystal would need (1 at the triple point, falling as T falls). Between 265.15 and 264.15 K the two cross and ice APPEARS — announced by the run between the two grid values it lies between, recorded as an appeared event in the result block, pinned as diag first_ice. From there down the liquor concentrates exactly along the freezing-point-depression identity

γ_w · x_w = exp(-ΔH_fus (1 - T/T_t) / (R T)), ΔH_fus = 6008 J/mol, T_t = 273.16 K

with every quantity from water.dat's own data — published at every point as a_water beside aEq_water, equal to 1e-10 wherever ice is present, and recomputed independently by the gate from the record. By -20 °C 63 % of the feed is ice and the liquor is 27 mol% ethanol.

What is published. freeze.csv (T first, then solved, nPhases, the amount of each phase — L1, ice — their compositions, the flash's own a_water / aEq_water / solidFraction) and the top-level result block



phaseSplitScans (points, the event, the record-level announcements at the first point that raised each, what is not modelled). Every number in the block is a CSV cell or a diagnostic, so the csv and diag golden kinds pin all of it: the golden carries the diagnostics and ten authored CSV cells (rows 9, 15, 20).

standardState01_hydrogen_enthalpy_TP

tutorials/props/thermo/standardState01_hydrogen_enthalpy_TP

What it does: h(T,P) of hydrogen on SRK, 300-1000 K by 1-1000 bar, 42 points: the ideal-gas part against the residual, for the standard-state EduTool

The story: One propertyPoint per node of the page's grid. Names are the keys the GUI reads: h_T<K>_P<bar>; h_converter is the green-ammonia converter's (T, P), h_converter_1bar its standard-pressure twin.

Witness of the standard-state EduTool (∗Enthalpy, the standard state and equilibrium: what does the ° mean?∗). Forty-two propertyPoint operations on hydrogen, one per node of the page's grid — 300 to 1000 K by 100 K, at 1, 100, 300, 600 and 1000 bar — plus the green-ammonia converter's state (733.15 K, 150 bar) and its 1 bar twin. Each publishes the three numbers the page separates: H_ig, the ideal-gas enthalpy (a function of temperature alone, on the elements datum — hydrogen is an element, so it is zero at 298.15 K); H_R, the SRK residual at the real temperature and pressure; and their sum H_real.

A table gives a standard enthalpy with a degree sign. Does the sign mean 1 bar? Does it also mean 25 °C? If the process runs at 150 bar, is using a standard property not assuming the gas is ideal? The page answers in the order a student can follow — behaviour first, then the reference, only then the symbol — and this case supplies the behaviour.

∗ Along 1 bar, heating from 300 to 1000 K raises the enthalpy by 20.64 kJ/mol. At 300 K, compressing from 1 to 1000 bar at constant temperature raises it by 1.29 kJ/mol; at 1000 K by 1.69. The pressure effect is an order of magnitude smaller than the temperature effect in this range, and it is not zero. ∗ At the converter's state the ideal-gas rise from 298.15 K is 12.73 kJ/mol and the residual adds 0.23 kJ/mol — 1.8 % of the rise. At 1 bar and the same temperature the residual is 1.5 J/mol: the real gas at the standard pressure is a hair from the ideal gas, and still not the same definition.

constant/experimental/hydrogen_Hmolar_leachman2009_coolprop.csv carries the same 42 states from a fundamental equation of state fitted to measurements — Leachman, Jacobsen, Penoncello & Lemmon, ∗J. Phys. Chem. Ref. Data∗ 38 (2009) 721–748, as implemented in CoolProp 8.0.0 (Bell et al., ∗Ind. Eng. Chem. Res.∗ 53 (2014) 2498; MIT licence). It is RE-COMPUTED here by bin/curate/reference_h2_enthalpy.py (–check re-derives every row), not pasted from anywhere, and it sits in constant/experimental/ because that is the one location the GUI bundle and .gitignore admit for a CSV that is a case input; its header says it is a model's output, not a measurement.

The two agree on the ideal-gas part to a few joules per mole over the whole range. They do not agree on the residual: SRK is 6 % below the reference at 300 K and 1000 bar, a third below at 300 K and 100 bar, 11 % below at the converter. Measured before the model was chosen: Peng-Robinson is worse here — a third below at 1000 bar and the wrong sign at 100 bar — so the case runs SRK and the page draws both sets and states the gap. Nothing was tuned; hydrogen's anomalous acentric factor (-0.220) is what a cubic equation handles poorly, and the page says so rather than hiding it.

A propertyScan2D would do this in one operation and write a CSV — which the browser cannot read back. The GUI reads each operation's diagnostics, so the grid is 42 point evaluations whose names (h_T<K>_P<bar>) are the keys the page looks up. The golden pins every one of them.

temperature01_gas_thermometer

tutorials/props/thermo/temperature01_gas_thermometer

What it does: The gas thermometer: why the ideal gas is a limit, not a substance

The story: A constant-volume gas thermometer reads a temperature off PV = nRT. A real gas does not obey that, so the reading depends on the PRESSURE it was taken at – and only in the limit P → 0 does it become the thermodynamic temperature. This case measures that departure, at the temperature the accompanying notes are about.

500.012 K is not a special temperature. It is the number the notes use to ask what the last digits of a temperature actually assert, and the scan is run there so the two are talking about the same state.

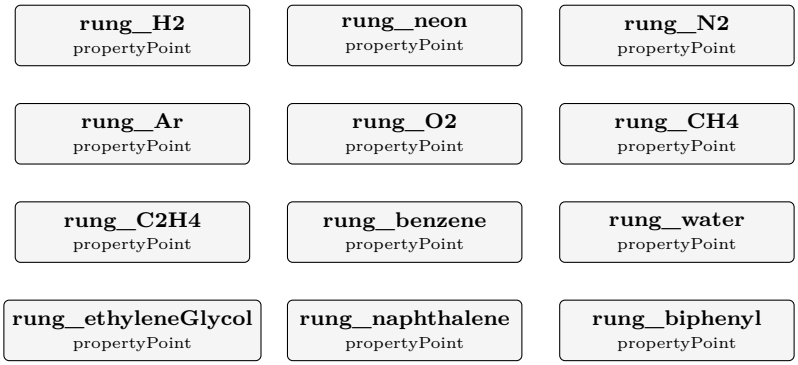
∗"Thermodynamics is a funny subject. The first time you go through it, you don't understand it at all. The second time you go through it, you think you understand it, except for one or two small points. The third time you go through it, you know you don't understand it, but by that time you are so used to it, it doesn't bother you any more."∗

— attributed to Arnold Sommerfeld. PROVENANCE UNVERIFIED: Sommerfeld published no such sentence; it reaches us by report, and this repository does not quote a source it has not read. It is here as an epigraph, marked, and must be either sourced or dropped before it appears in any published guide.

What does the 012 assert? Not "roughly five hundred kelvin" — three digits past the decimal point is a specific claim about the world. Whose claim, and resting on what?

The kelvin is no longer defined by a substance. It is defined by fixing the Boltzmann constant:

Not measured. Fixed. So a temperature is a conversion factor between energy and degrees, and nothing else. The triple point of water — which ∗defined∗ the kelvin for sixty-five years — became, overnight, a quantity that is measured, with an uncertainty.



That is the first dogma, and it is worth sitting with: the definition tells you what a kelvin ∗means∗ and gives you no way whatsoever to ∗measure∗ one.

temperature02_engineers_ladder

tutorials/props/thermo/temperature02_engineers_ladder

What it does: The range a chemical engineer actually works in

The story: THE LADDER A CHEMICAL ENGINEER ACTUALLY CLIMBS, and the engine CHECKS it rather than quoting it.

Each rung asks one question: at the temperature this substance's record calls its normal boiling point, what does its VAPOUR-PRESSURE CORRELATION say the pressure is? The answer should be one atmosphere – that is what a normal boiling point means – and how close it lands is a measure of the record, published rather than assumed.

THE OTHER WAY ROUND WOULD HAVE BEEN NICER AND DOES NOT WORK. Asking for 'T_bubble' at 1 atm solves for the temperature, which is the more direct question; 'BubblePoint::compute' carries its own initial guess and does not converge at 20 K, a gap this repository already has on record (see docs/design/held-out-pressure.md). Verifying the pressure at a declared temperature asks the same physics of the same correlation and is robust, so that is what runs here – said plainly rather than papered over.

WHY THE LADDER STOPS AT GLYCEROL, and it is not because the list got boring. Above roughly 600 K an ordinary organic does not have a normal boiling point to check: it CRACKS first, so there is no one-atmosphere equilibrium to ask about. The scale itself changes character there – ITS-90 stops interpolating on vapour pressure and gas thermometry altogether and realises its upper range on the FREEZING POINTS OF METALS, then on Planck radiation above the silver point. Those fixed points are declared values of the scale, not something this engine computes, and the page says so where it lists them.

DOWTHERM A IS ABSENT AND THAT IS A FINDING, not an oversight. The hot-oil fluid an engineer actually runs a 530 K loop on is curated here with 'role nonvolatile' and carries NO vapour-pressure correlation, so this case cannot ask it the question it asks the others. Named rather than quietly skipped: an omission a reader cannot see is the kind of gap this project refuses to leave.

Eight rungs, from liquid hydrogen to boiling water, checked by the engine rather than quoted at you.

At the temperature each substance's record calls its normal boiling point, what does its vapour-pressure correlation say the pressure is?

It should be one atmosphere — that is what a normal boiling point ∗means∗. How close it lands measures the record, and the answer is published rather than assumed.

The substance every engineer trusts most is the worst rung on the ladder.

Water's Antoine fit declares Trange (273 373). Its normal boiling point is 373.15 K. The fit stops 0.15 K before the temperature everybody uses it at, and evaluated there it returns 1.026 atm instead of 1.000 — 2.6 % out, on the one substance whose boiling point every reader could recite.

Seven cryogens the reader has no intuition for land inside 1.4 %. The familiar one does not. Familiarity is not accuracy, and a declared validity range is worth more than a feeling.

thermoTest

atoms01_formula_parser

tutorials/props/thermoTest/atoms01_formula_parser

What it does: The shared formula parser, opened up: nested groups, both hydrate spellings, an ion charge that is not an element

The story: THE FORMULA PARSER, WITH ITS LID OFF.

The element balance is only as good as the thing that reads a formula, so that reader is ONE piece of code (src/thermo/ElementComposition) and ‘elementalComposition‘ is its glass-box surface: give it a formula, see the atoms it counted.

The formulas here are chosen to be the awkward ones, because those are where a hand-rolled parser goes wrong:

C2H6O plain, the control; Ca(OH)2 a nested group with a multiplier – 2 O and 2 H, not 1; CaSO4:2H2O a HYDRATE, the colon form: 6 O in total, 4 from the sulfate and 2 from the two waters; MgSO4:7H2O the same salt, colon form: Mg 1, S 1, O 11, H 14; MgSO4.7H2O THE SAME SALT AS A CHEMIST WRITES IT, and the one formula here that is REFUSED. The ASCII ’.’ is ambiguous, and Choupo resolved it in favour of the decimal subscript – see sepiolite below – so this spelling would silently count the seven waters into the oxygen: O 5.7 and H 2 where the salt has O 11 and H 14. A wrong element balance from a spelling nobody would flag by eye. It refuses and names both unambiguous forms; Mg2Si3O7.5OH:3H2O why the dot cannot simply BE the hydrate separator: this is curated sepiolite, and its 7.5 is a real half-integer; SO4-2 an ION: the charge is not an element and must not become one; (NH4)2SO4 a nested group of a nested group’s worth of hydrogen – 8 H.

A parser that silently mis-reads any of these produces an element balance that closes on the wrong atoms, which is worse than one that refuses.

h_surface_identity

tutorials/props/thermoTest/h_surface_identity

What it does: The state identities of the canonical enthalpy surface: dh/dT == Cp_phase, the 298 K vaporisation anchor, and Kirchhoff on Hvap_state – pinned to round-off

The story: thermodynamics as a REGRESSION TEST.

A surface that anchors each phase leg on the 298.15 K formation datum and integrates the TARGET phase's own Cp obeys, by construction:

(1) dh_liq/dT = Cp_liquid(T) (2) dh_gas/dT = Cp_idealGas(T) (3) h_g(298.15) - h_liq(298.15) = Hvap(298.15) (the anchor) (4) d[h_g - h_liq]/dT = Cp_g - Cp_liq (Kirchhoff)

This op checks all four by central finite difference for benzene, toluene, water and ethanol at 350 K and REFUSES above 1e-6 relative error – so no future "convenient" leg (a Watson-slope liquid, a mixed-datum gas) can re-enter the balances unnoticed. The golden pins every per-species error.

model4_speciation_scaling

tutorials/props/thermoTest/model4_speciation_scaling

What it does: RO membrane-scaling audit of a brackish groundwater: aqueous speciation (Davies) with pH SOLVED from electroneutrality (the feed charge imbalance is announced first) + saturation indices SI = log10(IAP/K), scanned over water recovery to r = 0.85 (concentrate = feed/(1-r)) TWICE: closed system (DIC conserved and concentrating) vs open to the atmosphere (a(CO2aq) pinned by Henry at pCO2 = 4.2e-4 atm, DIC a solved outcome – this CO2-rich water degasses, pH and calcite SI jump above the closed curve) – the calcite SI curves differ; that contrast is the lesson. Three analytic pins lock the physics: pure water at given pH 7 reproduces Kw (m_OH ~ 1e-7), a back-computed gypsum-saturated CaSO4 solution gives SI_gypsum ~ 0.00, and pure water with pH solved lands at exactly 7.000.

The story: thermoTest / model4_speciation_scaling

The SAME system {NaCl, CaSO4, water} in its THIRD role: a MULTI-ION broth. Here we no longer think of "NaCl" or "CaSO4" – the aqueous speciation engine reasons in the shared ions Na+, Cl-, Ca2+, SO4-2 (plus the neutral ion pair CaSO4aq), and reports SATURATION INDICES SI = log10(IAP/Ksp) for every solid the ions can form: gypsum (CaSO4.2H2O) and halite (NaCl).

Na+ comes from NaCl, Cl- from NaCl, Ca2+/SO4-2 from CaSO4 – but once dissolved there are no salt boundaries, only ions. This is why a "salt" cannot carry its own activity model: the ion pool is shared (the species/ tier of the tree).

MODEL: Pitzer-HMW is MANDATORY here. The ionic strength is I ~ 3.3 mol/kg (NaCl-dominated); the Davies law is only trustworthy to I ~ 0.5 m, so the ‘activityModel‘ is declared explicitly (no silent default) – with Davies the saturation indices at this I are quantitatively meaningless.

The brine is NaCl-dominated (3 mol/kg, near seawater) with CaSO4 (0.10 mol/kg) right at gypsum saturation (SI ~ 0). Charge balances exactly (Na + 2 Ca = Cl + 2 SO4), so pH is pinned at 7. The scan concentrates the brine (evaporation; r = fraction of water removed): gypsum scales first, at r ~ 0.035 (it starts saturated), halite only near r ~ 0.50. Note m_CaSO4aq ~ 0.005: the neutral ion pair is a real fraction of the calcium – "dissociation" is partial.

transport

transport01_gas_bench

tutorials/props/transport/transport01_gas_bench

What it does: Every transport correlation proves itself against its own anchor – theory or arithmetic, said which – and then all are asked the same question for four gases at 373 K; NOTHING here is measured

The story: transport01 – THE TRANSPORT CORRELATIONS, AS OBJECTS THAT PROVE THEMSELVES.

NOTHING IN THIS CASE IS MEASURED. Read that first. Choupo's catalogue carries no measured gas viscosity, thermal conductivity or diffusivity, so no number below is compared with an experiment. What the case shows is what CAN be shown without one, and it says which kind each check is:

THEORY an identity kinetic theory or the correlation's own author supplies – Eucken on a monatomic gas MUST give the Chapman-Enskog lambda = (15/4) R mu / M exactly; Wilke's phi_ii MUST be 1 for identical species. A wrong constant fails here. ARITHMETIC the correlation's own closed form at a stated point, written as a literal – Chung's Neufeld Omega at T∗ = 1, Fuller at round numbers, Sato-Riedel at T = Tb where its bracket ratio is 1 by construction, the fitted liquid forms reducing to Andrade. This checks the TRANSCRIPTION and the units, and the output says so rather than letting 0.0000 % read as a validation.

WHAT THE RUN DOES, IN TWO PARTS. (1) VERIFY. Every registered model in five families, plus the shared gas mixing rule, reproduces its own anchor; each prints its window, its PRIMARY citation and the anchor's kind. (2) COMPARE. N2, O2, CO2 and water vapour at 373.15 K, 1 bar: every registered gas-viscosity and gas-conductivity model for every component, each with its computable window verdict (Chung's T∗ against the Neufeld domain; Eucken's "polyatomic" by the record's own Cp), then the case's mixing rules – Wilke for mu, Wassiljewa / Mason-Saxena for k – at the equimolar composition (announced).

WHAT TO READ IN THE OUTPUT. Three things. The spread across models is 0.00 % – for BOTH gas families – and the bench says why: ONE model is registered per family. A spread over one is not agreement; Chapman-Enskog (Lennard-Jones sigma and eps/k, which no record carries yet) is the named next member. Chung ANNOUNCES, for each of the four components, that Vc was estimated from Zc(omega) and that the polar and association terms were dropped. Water is polar; the announcement is the only thing in the run that says the non-polar form was applied to it anyway. Eucken flags CO2 and water (and, by their Cp, N2 and O2 – diatomics are polyatomic) as APPROXIMATION HERE, because plain Eucken is exact only for a monatomic gas and this case has none.

WHAT THIS CASE DOES NOT DO. It does not say which model is right, and it does not compare with a measurement. The golden pins that the anchors, the values and the (absent) spread have not MOVED – nothing more. Record: docs/design/transport-correlations-as-objects.md.

transport02_chapman_enskog

tutorials/props/transport/transport02_chapman_enskog

What it does: Chapman-Enskog from Svehla's own force constants: seven gases at 300 K priced by two viscosity and two conductivity models, the spread a real disagreement for the first time; nothing measured here, the sigma/eps-k are Svehla's fits to pre-1962 viscosities, cited by page

The story: transport02 – CHAPMAN-ENSKOG FROM SVEHLA'S CONSTANTS, AND THE FIRST REAL SPREAD.

NOTHING IN THIS CASE IS MEASURED, except in the one sense the anchors state. The seven Lennard-Jones pairs (sigma, eps/k) on the records in constant/components/ are Svehla's LEAST-SQUARES FITS to viscosities measured before 1962 (his Table I(a) method 1, one row per gas, cited by report page in each record's own provenance block); Choupo holds none of those measurements and compares with none. What the run shows:

TWO models per gas family, so the spread column is a DISAGREEMENT and not the 0.00 % of transport01: Chung (corresponding states from Tc, Pc, omega – non-polar truncation, Vc estimated, both announced) beside Chapman-Enskog (kinetic theory over the fitted sigma, eps/k); plain Eucken beside the modified Eucken (Svehla eq. (2), the internal modes weighted 1.32). Water is where the two viscosities part furthest: Chung's non-polar form against a pair FITTED to steam data. Argon is the control: monatomic, so Eucken and the modified Eucken coincide to the extent the record's Cp polynomial returns 5R/2 (it does, to four figures at 300 K; lambda" is the residual) and the polyatomic flag stays silent. Every Chapman-Enskog component is ANNOUNCED with the ORIGIN of both constants (FITTED to measured transport data, Svehla method 1) and the page they were read from; an estimated pair would say ESTIMATED in the same place. The window verdict is T∗ = kT/eps against the Neufeld fit's 0.3 <= T∗ <= 100; water at 300 K sits at T∗ = 0.37, inside, near the low edge. The comparison point is 300 K, 1 bar – the 300 K row of Svehla's Table III – so a reader can set the printed viscosities beside his (report pages 31 Ar, 56 CH4, 58 CO2, 74 H2, 75 H2O, 90 N2, 98 O2) and see the residual the anchor row measures: the Neufeld 1972 fit of the collision integral against the Hirschfelder 1954 tables he interpolated, 0.1-0.8 % across these gases, 1.8 % for water.

THE ANCHORS. ChapmanEnskog: ARITHMETIC – with Svehla's own M, sigma, eps/k for N2 the engine returns his printed eta at 300 K (report page 90) within a DECLARED 1 % (0.40 % observed); it checks the constant 26.693, the unit chain and the shared collision-integral home, nothing about any gas. modifiedEucken: THEORY – a monatomic gas must give exactly (15/4) R mu / M – after reproducing Svehla's printed N2 conductivity from his own eta and Cp/R through eq. (2). The bench prints the kind.

WHAT THIS CASE DOES NOT DO. It does not say which viscosity is right for water or for anything else, and it does not compare with a measurement. The records are CASE-LOCAL (adopted, on the edwards02 precedent): the public catalogue carries no lennardJones block until Vitor promotes one; bin/curate/propose_lennard_jones.py drafts them into data/local/ from the committed transcription bin/curate/svehla1962/. Binary diffusivity by Chapman-Enskog is NOT here: the Omega(1,1)∗ fit is not citable from any source in the tree. Record: docs/design/transport-correlations-as-objects.md, section 8.

Category IV: Batch and time-dependent (choupoBatch)

$\mathrm{d}\mathbf{Y}/\mathrm{d}t = f(\mathbf{Y})$ integrated in real time, with recipes for discrete events; trajectories, not steady states.

adsorber

The theory you need. Adsorption in a vessel or a bed: the isotherm $q^*(T, p)$ (Langmuir $q = q_{\max} bp/(1+bp)$, van't Hoff $b(T)$) is the curated PAIR datum; the LDF rate $\mathrm{d}q/\mathrm{d}t = k\,(q^* - q)$ carries the EQUIPMENT datum k (this particle, this bed – it lives in the case, never the catalogue). Work the cases as a staircase. `batch09`: a closed vessel relaxes to the inventory equilibrium – one algebraic root, pinned independently of the run. `batch10`: two species compete for the same sites (extended Langmuir) – the selectivity is an equilibrium statement, and the model's Gibbs–Duhem inconsistency for unequal $q_{\max}$ is declared, not hidden. `batch11`: in the Henry limit the whole vessel is LINEAR and the integrator must match $q_\infty(1 - e^{-k_{\mathrm{eff}}t})$ to 10^{-8} – the analytic gate. `batch12`: declaring the headspace pressure AND the inventory over-specifies a closed ideal-gas vessel – the contradiction FATALs; P is a result. `batch13`: the fixed bed – the stoichiometric time $t_{\mathrm{st}} = (L/u)(\varepsilon + \rho_b q^*/c_{\mathrm{in}})$ is announced BEFORE integration, breakthrough spreads around it, and the constant-u closure's fabricated carrier is printed, pinned and discounted: the DECLARED model residual is itself the lesson. `batch14`/`batch15` are the numerical hygiene: pure transport vs the analytic advection–dispersion solution, and the mesh study that earns $N = 100$. *Full derivation: Theory Guide, the adsorption chapter.*

batch09_adsorber_co2

tutorials/batch/adsorber/batch09_adsorber_co2

What it does: Closed isothermal CO2 uptake on zeolite 13X (LDF, solid film): the vessel relaxes to the inventory equilibrium p_inf = 7229.13 Pa, q_inf = 1.9708 mol/kg

The story: closed, isothermal gas–solid uptake vessel.

2 mol of pure CO2 in a 0.01 m3 ideal-gas headspace over 1 kg of regenerated zeolite 13X at 298.15 K. Linear-driving-force kinetics on the solid film (dq/dt = k∗(q∗ - q), k = 0.05 1/s, equipment data, this case's sample) against the competitive-Langmuir equilibrium record of the pair catalogue (here a single pair, CO2/zeolite13X: q_max = 5.0 mol/kg, b_298 = 9.0 1/bar, dH_ads = -45 kJ/mol).

The final state is FIXED BY INVENTORY, not by kinetics: with n_gas = p V/(R T) and q = q_max b (p/1e5)/(1 + b p/1e5),

p V/(R T) + m_ads ∗ q_max ∗ b ∗ (p/1e5)/(1 + b∗(p/1e5)) = n0

whose root at 298.15 K is (a2_vectors.py, 10 digits)

p_inf = 7229.128209 Pa q_inf = 1.970838025 mol/kg n_gas = 0.02916197467 mol uptake = 1.970838025 mol (98.54 %) tau (linearised at the equilibrium) = 0.4768 s

The run must reproduce these to the golden tolerances – an independent analytic anchor, not a mirror of the code. The ODE state is ONLY q; n_gas is algebraic (n_tot - m_ads∗q), so the per-species closure column closure_worst_rel in trajectory.csv is exact by construction (<= 1e-13). Log: the unit announces the ideal-gas assumption, the initialLoading default, the RK4 stiffness bound and the isosteric-KPI label at start-up.

batch10_adsorber_co2_n2

tutorials/batch/adsorber/batch10_adsorber_co2_n2

What it does: Closed isothermal competitive CO2/N2 uptake on zeolite 13X: extended-Langmuir site competition drives the equilibrium selectivity S = 71.43

The story: COMPETITIVE binary uptake, closed vessel.

0.5 mol CO2 + 1.5 mol N2 in a 0.01 m3 ideal-gas headspace over 1 kg of regenerated zeolite 13X at 298.15 K. Both species carry an isotherm record (extended Langmuir: CO2 q_max 5.0 / b_298 9.0 1/bar; N2 3.5 / 0.18 1/bar) and both carry a declared LDF constant – so both integrate, and the strong adsorbate suppresses the weak one through the SHARED site denominator 1 + Sum_j b_j p_j.

The final state solves the 2-species inventory system n_gas_i + m_ads ∗ q_i(p_CO2, p_N2) = n0_i, p_i = n_gas_i R T / V whose root (a2_vectors.py, Newton residual 0):

CO2: p_inf = 0.01611568794 bar q = 0.4934990047 mol/kg N2 : p_inf = 1.802652166 bar q = 0.7728183086 mol/kg P_total = 181876.7854 Pa selectivity S = (q_CO2/q_N2)/(p_CO2/p_N2) = 71.42857143 = (q_max∗b)_CO2/(q_max∗b)_N2 (extended-Langmuir identity)

The golden pins the COMPETITIVE path: get the shared denominator wrong and every one of these numbers moves. closure_worst_rel stays exact by construction (state = q only; n_gas algebraic).

What to expect (golden-locked):

batch11_adsorber_henry

tutorials/batch/adsorber/batch11_adsorber_henry

What it does: Closed isothermal Henry-limit uptake (linear isotherm): the coupled gas+solid system is LINEAR and the run must match q(t) = q_inf∗(1 - exp(-k_eff t)) to 1e-8

The story: the EXACT-solution gate (G1a of the A2 spec).

1 mol of CO2 in a 0.01 m3 ideal-gas headspace over 1 kg of a SYNTHETIC Henry-limit sorbent (linear isotherm q∗ = K_H p, K_H = 0.4 mol/(kg bar) at 298.15 K – a teaching record, vendored case-local). With a linear isotherm and one species the coupled vessel is LINEAR and closes in analytic form:

alpha = K_H[mol/(kg Pa)] ∗ R∗T/V = 0.9915828118 1/kg k_eff = k ∗ (1 + alpha∗m_ads) = 0.09957914059 1/s q_inf = alpha∗n0 / (1 + alpha∗m) = 0.4978868094 mol/kg q(t) = q_inf ∗ (1 - exp(-k_eff∗t)) (q0 = 0)

q(5) = 0.1952670621 q(10) = 0.3139520079 q(30) = 0.4727835287 q(60) = 0.4966211107 mol/kg

The pedagogical point the closed vessel adds over the fixed-q∗ packet formula: k_eff > k – gas depletion ACCELERATES the approach to equilibrium (the packet's q∗ = const law is the V_gas → infinity limit of this same solution). The trajectory rows at t = 5/10/30/60 s must match the table above to 1e-8 mol/kg (RK4 dt = 0.01 s); the golden pins the t = 60 s state.

What to expect (golden-locked):

kind	unit/stream	key	expected
kpi	adsorber	P_final	124785.4636

batch12_adsorber_refused_P

tutorials/batch/adsorber/batch12_adsorber_refused_P

What it does: REFUSAL lesson: declared initial.P (10 bar) contradicts n∗R∗T/V (4.958 bar) – the honest cross-check FATALs; P of a closed ideal-gas headspace is a result, not an input

The story: the REFUSAL lesson (deliberate, must FAIL).

Identical to batch09_adsorber_co2 EXCEPT initial.P declares 10 bar while n∗R∗T/V = 4.9579 bar. P of a closed ideal-gas headspace is a RESULT (n, T, V fix it – Duhem); a declared P is honoured only as an honest cross-check, and a relative deviation > 1e-3 REFUSES, printing both numbers. Expected FATAL (exit != 0):

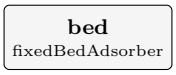
batchAdsorber 'adsorber': declared P inconsistent with n∗R∗T/V – initial.P = 1e+06 Pa (10 bar) but n∗R∗T/V = 495791 Pa (4.95791 bar), relative deviation 1.01698 > 1e-3. ...

Marked .expect-nonconvergence: counted EXPECTED-FAIL by runTests, never green, never recordable. Base case (the passing twin):

2 mol of pure CO2 in a 0.01 m3 ideal-gas headspace over 1 kg of regenerated zeolite 13X at 298.15 K. Linear-driving-force kinetics on the solid film (dq/dt = k∗(q∗ - q), k = 0.05 1/s, equipment data, this case's sample) against the competitive-Langmuir equilibrium record of the pair catalogue (here a single pair, CO2/zeolite13X: q_max = 5.0 mol/kg, b_298 = 9.0 1/bar, dH_ads = -45 kJ/mol).

The final state is FIXED BY INVENTORY, not by kinetics: with n_gas = p V/(R T) and q = q_max b (p/1e5)/(1 + b p/1e5),

p V/(R T) + m_ads ∗ q_max ∗ b ∗ (p/1e5)/(1 + b∗(p/1e5)) = n0



whose root at 298.15 K is (a2_vectors.py, 10 digits)

p_inf = 7229.128209 Pa q_inf = 1.970838025 mol/kg n_gas = 0.02916197467 mol uptake = 1.970838025 mol (98.54 %) tau (linearised at the equilibrium) = 0.4768 s

The run must reproduce these to the golden tolerances – an independent analytic anchor, not a mirror of the code. The ODE state is ONLY q; n_gas is algebraic (n_tot - m_ads∗q), so the per-species closure column closure_worst_rel in trajectory.csv is exact by construction (<= 1e-13). Log: the unit announces the ideal-gas assumption, the initialLoading default, the RK4 stiffness bound and the isosteric-KPI label at start-up.

batch13_breakthrough_co2

tutorials/batch/adsorber/batch13_breakthrough_co2

What it does: CO2 15%/He breakthrough on zeolite 13X – 1-D isothermal fixed bed (A3): t_st = 3040.5 s announced pre-run, t_b(5%) = 2890.7 s, ledger closure at machine level

The story: CO2/He breakthrough on a zeolite-13X bed.

THE A3 anchor case (spec 2026-07-12): a 0.5 m isothermal fixed bed of zeolite 13X, fed 15% CO2 in helium at u = 0.05 m/s superficial, 1 bar, 298 K. Helium carries NO isotherm record on 13X → announced inert CARRIER, transported but never adsorbed, closed by difference from the constant c_tot = P/(RT). At 15% CO2 this is NOT a dilute approximation: the constant-(u, P, T) closure implies He at the net uptake rate, and the campaign books it as a NAMED INLET STREAM of the bed, ‘carrierMakeUp‘ ("carrier implied by the constant-(u, P, T) assumption"), so mass and element balances close and the stream is the explanation; its size is the assumption’s size (KPIs carrier_fabricated_mol, carrier_makeup_rel); the genuinely clean transport anchor is batch14. The engine announces, BEFORE integrating, where the front must arrive:

q∗(c_in) = 5∗9∗0.15/(1 + 9∗0.15) = 2.872340426 mol/kg R_f = eps + rho_b q∗ / c_in = 304.0512509 t_st = (L/u) R_f = 3040.512509 s u_sh = u/R_f = 1.644459605e-4 m/s

Independent gates this run must reproduce (anchors_a3.py, FV N = 100):

t_b(5%) = 2890.669098 s t_50 = 3036.448293 s t_b(95%) = 3204.166058 s INT(1 - c_out/c_in)dt = t_st to 2.2e-10 (telescopic FV conservation) ledger mass closure <= 1e-10 (IN/OUT integrated as rows of the SAME ODE)

Numerics: conservative FV, nCells = 100 DECLARED (do the 25/50/100/200 mesh study – batch15 publishes it: first-order upwind, observed order ~1.03-1.05), Danckwerts inlet as the imposed face flux u∗c_in, outlet dc/dz = 0. u, P, T are DECLARED constants of this phase, and the price is said OUT LOUD: the real velocity drops ~15% across the uptake zone, so the constant-u closure FABRICATES carrier (He) at exactly the net uptake rate (9.19 mol here) – announced in the run header, pinned as the KPI carrier_fabricated_mol and booked as the ‘carrierMakeUp‘ inlet stream of the campaign ledger; Ergun (‘flowModel ergun‘) needs no such stream, and the energy balance of this closure stays UNAVAILABLE (named).

Log: run header prints the hypotheses, the derived rho_p, Pe = 250, the Gershgorin step bound term by term and the stiffness verdict; profiles land in <t>/bed.profile every 100 s; trajectory.csv carries c_out, y_out, qbar and the per-species ledger closure.

What to expect (golden-locked):

kind	unit/stream	key	expected

batch14_transport_only

tutorials/batch/adsorber/batch14_transport_only

What it does: Pure transport (k = 0) on the batch13 bed, N = 200: t_50 vs the Ogata-Banks analytic ADE solution (gate G1) under fixed RK4 with the Gershgorin bound printed term by term

The story: the k = 0 transport gate (A3 spec, gate G1).

Same bed, same feed, same mesh family as batch13 – but the LDF constant is DECLARED ZERO: the solid is frozen and CO2 crosses the bed as a pure tracer. What is left is exactly the advection-dispersion equation with a Danckwerts inlet, and THAT has an analytic yardstick (Ogata-Banks, semi-infinite ADE; the finite-domain difference is O(1/Pe) = 0.4% at Pe = 250):

u_i = u/eps = 0.125 m/s D_i = Dax/eps = 2.5e-4 m2/s c/c0 (L, 3.5 s) = 0.07340274358 c/c0 (L, 4.0 s) = 0.5178057707 c/c0 (L, 4.5 s) = 0.913645218 t_50 analytic = 3.984074227 s

FV yardsticks pinned by this case (anchors_a3.py, N = 200):

t_50 numeric = 3.975611088 s (0.21% below analytic – first-order upwind; the deviation HALVES with each mesh doubling: 1.40% at N=25, 0.74% at 50, 0.40% at 100, 0.21% at 200, 0.11% at 400) INT(1 - c_out/c_in)dt = eps L / u = 4.0 s (telescopic conservation: exact identity once saturated) ledger closure ~ 1e-14 (k = 0)

A declared zero is not a silent default: the unit announces "k = 0 DECLARED: transport-only diagnostic, the solid is frozen (gate G1)". Note the He carrier fabrication of batch13 vanishes here (no uptake): carrier_fabricated_mol = 0.

What to expect (golden-locked):

kind	unit/stream	key	expected

batch15_mesh_study

tutorials/batch/adsorber/batch15_mesh_study

What it does: Mesh-study member N = 25 of the batch13 breakthrough: t_b(5%) converges monotonically 2732 → 2839 → 2891 → 2916 s with observed order 1.03-1.05; full table in reports/meshStudy.md

The story: the declared-mesh lesson (A3 spec, gate G6).

The axial mesh is a DECLARED modelling choice (nCells; absent = FATAL), and this case is the receipt: the batch13 breakthrough run on the 25/50/100/200 family, everything else identical. First-order upwind advection dominates the error, so t_b(5%) must converge MONOTONICALLY with observed order p ~ 1:

N = 25 t_b5 = 2732.027658 s (this case) N = 50 t_b5 = 2838.542518 s N = 100 t_b5 = 2890.669098 s (batch13, the production mesh) N = 200 t_b5 = 2915.764796 s p(25/50/100) = 1.031 p(50/100/200) = 1.055 Richardson (p = 1): t_b5(inf) ~ 2940.86 s → N = 100 sits 1.7% low

The full table, the four overlaid breakthrough curves and the verdict are PUBLISHED in reports/meshStudy.md (generated from the four runs; the report header cites mesh, tolerances and integrator). The ledger mass closure stays <= ~1e-11 on EVERY mesh – conservation is telescopic in the FV form, it does not improve with refinement because it was never discretisation-limited (gate G3).

This case pins the N = 25 member; its numbers are DELIBERATELY the worst of the family (t_b5 5.8% below batch13) – coarse-mesh optimism made visible, the point of the lesson.

batch19_feed_switch_purge

tutorials/batch/adsorber/batch19_feed_switch_purge

What it does: A5 feed switch: CO2/He load to 3600 s (batch13 anchors), then pure-He purge to 9000 s – amended feed commitment ledgered, frozen breakthrough KPIs, desorption duty as the same state difference

The story: THE A5 WITNESS: load, then switch the feed.

batch13's bed (CO2 15% in He on zeolite 13X, the A3 anchor), run through a TWO-STEP cycle in one campaign:

0 .. 3600 s LOAD – identical to batch13's feed; the front arrives on the batch13 anchors (t_5 = 2890.7, t_50 = 3036.4, t_95 = 3204.2 s) 3600 s SWITCH – recipe setParameter bed.feed.CO2 = 0: the feed becomes pure He (concentration- swing regeneration) 3600 .. 9000 s PURGE – $q*(c \to 0) = 0$, the LDF drives the bed to desorb; the favourable (Langmuir) isotherm makes desorption the UNFAVOURABLE direction – watch the long tail on c_out

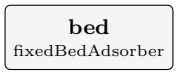
What the switch does, and where each consequence is VISIBLE:

The feed commitment is DECLARED matter (the campaign datum owns A∗u∗c_in∗(endTime - t) of future feed). Re-declaring the feed at t = 3600 s AMENDS that commitment: the un-fed CO2 leaves the datum and the extra He enters it, priced and recorded as 'feedAmendment' ledger records against the external boundary – the campaign mass/element balances read the records and still close (KPIs mass_kg_amend_in/out, element_worst_closure_vs_declared_rel ~ 1e-14).

The breakthrough sampler's reference basis (c_out/c_in) dies with the old feed: crossings and integral FREEZE at their pre-switch values (announced), so t_5/t_50/t_95 here must MATCH batch13's anchors – the frozen claim describes the first feed step. The desorption wave lives on in the trajectory's c_out_CO2 / qbar_CO2 columns.

The adsorption duty stays an EXACT state difference on the adsorbed inventory: E_adsorption = dH_ads ∗ (n_ads(end) - n_ads(0)). batch13 (load only) ledgers -413.6 kJ; here the purge takes part of the loading back OUT, so |E| is SMALLER – desorption is endothermic and the ledger shows the heat returning, with no new formula anywhere.

u, P, T stay DECLARED CONSTANTS: asking the bed for a thermal swing (feed.T), a flow transient (u) or a blowdown (P) is REFUSED by name (fired by bin/curate/check_feed_switch.py, batch12-style honesty).



The carrier-fabrication caveat of the constant-(u, P, T) closure applies unchanged: the carrier it implies is booked as the named stream 'carrierMakeUp' (an inlet while the bed loads, an outlet on the purge's net desorption), so the He element closure holds and the stream is the explanation.

batch20_thermal_breakthrough

tutorials/batch/adsorber/batch20_thermal_breakthrough

What it does: A5-T1 adiabatic CO2/He breakthrough (ergun, one T per cell): thermal wave + earlier front vs batch18, anchors u_th and DT_ad announced pre-run, campaign energy on vessel enthalpy alone

The story: THE A5-T1 WITNESS: the adiabatic bed.

batch18's ergun-mode bed (15% CO2/He, N = 25) with the energy balance DECLARED: 'energyBalance adiabatic;' – one temperature per cell, the isosteric heat staying IN the bed as a travelling thermal wave instead of being removed by an unnamed coolant. Design record: docs/design/fixed-bed-thermal-a5.md.

What the engine announces BEFORE integrating (equilibrium theory):

pure thermal-wave velocity u_th = u c_tot cpg / (eps c_tot cpg + rho_b cp_s) and the time L/u_th the heat needs to LEAVE the bed; the adiabatic LIMIT DT_ad = q∗(-dH_ads)/(cp_s + q∗ cpg_CO2 + eps c_tot cpg/rho_b) – the all-heat-retained BOUND (the loaded solid carries the adsorbate's own Cp). Here u_th < u_sh: the heat LAGS the front, so the observed outlet-T rise sits well BELOW the bound (~ +36 K vs the 126 K limit) while the WARM bed breaks through far earlier than batch18's isothermal front (t_50 ~ 812 s vs 3042 s – q∗(T) falls via the van't Hoff b(T), the SAME datum the energy state carries; one dH_ads, three readers).

The golden pins T_out/T_max, both anchors, the early crossings, and the campaign ENERGY closure – claimed, adiabatically, on the vessel's internal energy against the boundary streams alone, and closed to round-off: the bed's energy rows are conservative finite volumes (each cell's internal energy U_j, the faces carrying the enthalpy of the species fluxes; DEV.md 4c C258).

cp_s enters as DECLARED case data (the kLDF pattern – scope + source say where the number came from; curating a primary-cited cp onto the adsorbent asset record is a separate curation act). The adsorbed phase carries its gas's own Cp: a constant isosteric heat implies it (h_ads = h_gas(T) + dH_ads). Feed enters at the declared T; each raffinate package carries the enthalpy the outlet face integrated over its window and leaves at its mixing-cup T, so the material ledger carries the thermal wave's enthalpy exactly.

Adiabatic means NO energy record: nothing is exchanged with the environment; the campaign energy balance closes on the vessel's internal energy (per cell: gas n(h - RT) and adsorbed n(h + dH_ads) at T_j, solid sensible cp_s(T_j-T0)) against the boundary streams alone.

batch21_tsa_hot_purge

tutorials/batch/adsorber/batch21_tsa_hot_purge

What it does: T1.5 TSA half-cycle: adiabatic load to 3600 s, then 400 K clean He purge – feed.T as the hot-purge control, the re-declared commitment ledgered OUT at 298 K / IN at 400 K, energy balance claimed across the swing

The story: THE T1.5 WITNESS: a real TSA half-cycle.

batch20's adiabatic bed run as LOAD → HOT CLEAN PURGE in one campaign:

0 .. 3600 s LOAD – 15% CO2/He at 298.15 K (batch20's feed; the warm front is through by ~806 s) 3600 s SWITCH – recipe, two setParameter events: feed.CO2 = 0 (clean He purge) feed.T = 400 K (the HOT purge) 3600 .. 12000 s PURGE – the hot clean carrier sweeps the bed: q∗(T) collapses via the van't Hoff b(T) and desorption runs FAR faster than batch19's cold concentration swing

This is the step the old refusal named: "thermal swing needs the non-isothermal bed energy balance". A5-T1 built that balance; feed.T is now the hot-purge CONTROL (in thermal mode ONLY – the isothermal bed still refuses it, by name).

The LEDGER story is the point. A feed at a new temperature re-declares the WHOLE remaining commitment – at the pinned feed pressure the total concentration drops to P/(R∗400) (composition preserved) and even unchanged matter changes enthalpy – so the switch retires the old commitment (one OUT feedAmendment package, all species, at 298.15 K) and declares the new one (one IN package at 400 K): the enthalpy repricing rides in the packages' own T, and the campaign energy balance stays CLAIMED across the swing, boundary streams alone.

Breakthrough crossings/integral freeze at the switch (they describe the load step); the desorption story lives in c_out/qbar/T_out. The frozen pre-run anchors (u_th, DT_ad bound) keep their initialise values – a later switch never rewrites an announced claim.

batch22_wall_cooled

tutorials/batch/adsorber/batch22_wall_cooled

What it does: T2 wall-cooled CO2/He breakthrough (h=5 W/m2K, T_wall=298.15 K): the bed BETWEEN its limits – t_50 bracketed by the adiabatic 806 s and isothermal 3036 s, Q_wall as a state row of the same ODE, wallHeat record read from the state

The story: THE T2 WITNESS: the bed between its two limits.

batch20's adiabatic bed with 'energyBalance wallCooled;' – the energy row gains -h a_w (T_j - T_wall) and the bed sits BETWEEN the limits it must contain:

h → 0 batch20 (adiabatic: t_50 = 806 s, T_max ~ 336 K) h → infinity batch18 (isothermal: t_50 = 3036 s, T = T_wall)

so the golden pins the BRACKETING:

t_50(adiabatic) < t_50(wallCooled) < t_50(isothermal) T_wall < T_max(wallCooled) < T_max(adiabatic)

at h = 5 W/(m2 K), T_wall = 298.15 K, dBed 0.113 m DECLARED (never derived from the cross-section by a silent circle assumption); the engine announces a_w = 4/dBed and the wall NTU before integrating.

The LEDGER is the design point (docs/design/fixed-bed-thermal-a5.md section 6): the removed heat integrates as ONE MORE STATE ROW of the same ODE – the M_in/M_out ledger-row pattern – so the 'wallHeat' energy record READS a state (E = -Q_wall, T_service = T_wall) and the campaign closure dH_vessels = Q_ledger + H_external holds with every term a state function. Guards: 'adiabatic' + a wallHeatTransfer block refuses (contradiction), 'wallCooled' without one refuses, h <= 0 refuses (adiabatic is the way to SAY zero) – gate check_thermal_bed.

batch23_tsa_cycles

tutorials/batch/adsorber/batch23_tsa_cycles

What it does: Toward A6: three hand-declared TSA cycles (cold load / 400 K purge) in one campaign – eleven ledgered feed amendments, balances closed, final KPIs at the cycle boundary; the CSS verdict machinery stays a named proposal

The story: toward A6: three FULL TSA cycles, hand-declared.

batch21's half-cycle repeated three times in ONE campaign, with the recipe grammar that already exists – nothing new in the engine:

cycle k (k = 0,1,2), each 7200 s: t = 7200k feed.T = 298.15 K (cold again) [k>0] feed.CO2 = 0.15 (feed returns) [k>0] t = 7200k + 3600 feed.CO2 = 0 (clean purge) feed.T = 400 K (hot purge)

ending EXACTLY at the third cycle boundary (21600 s), so the FINAL KPIs are end-of-cycle values. Every switch re-declares the feed commitment through the T1.5 ledger machinery (the T switches retire and redeclare the WHOLE commitment; the composition switches amend by delta) – FIFTEEN feedAmendment records (three per switching instant: the composition delta + the T retire/declare pair), and the campaign mass/element/energy balances still close on records, never jumps.

The A6 QUESTION this case makes visible (and does not yet verdict): does the bed state at successive cycle ends approach a fixed point – the cyclic steady state? MEASURED (this case's own run): qbar_CO2 at the three cycle ends is 0.3151 → 0.2415 → 0.1748 mol/kg – a slow geometric approach (ratio ~0.9; each purge leaves residual heat, the next load starts warmer and holds less), NOT yet converged in three cycles. That unfinished convergence IS the pedagogical point: eyes on a trajectory can see it, and only the A6 verdict machinery could CLAIM it. The golden pins the third-cycle end. A first-class CSS verdict (declared cycles, per- cycle state snapshots, an invariance tolerance the case declares) is an ARCHITECTURE feature – proposed in docs/design/fixed-bed-thermal-a5.md section 7, awaiting Vitor's decision; this case is deliberately its cheap, grammar-free witness.

TIME INTEGRATION: 'solver { method rodas4; }' selects the order-4 stiff integrator (Hairer & Wanner's RODAS4) instead of the default 2(3) Rosenbrock pair. Same rtol, same Jacobian, same golden: 2.4x fewer steps and about half the wall clock on this case (it is the witness for that option; the other adsorber cases keep the default).

batch24_blowdown_inert

tutorials/batch/adsorber/batch24_blowdown_inert

What it does: P-swing witness A: inert isothermal blowdown, n/n0 = P/P0

The story: P-SWING WITNESS A: the inventory ratio.

The MATERIAL half of a blowdown, isolated from every thermal effect so it cannot pass by coincidence (design note fixed-bed-thermal-a5.md, section 8/9 amended battery, second-opinion review 2026-08-03):

ideal gas, INERT bed (kLDF = 0: the solid is frozen, pure transport), pure He; ISOTHERMAL ergun mode – T is a DECLARED constant of this teaching slice, so the energy question is out of frame BY DECLARATION (the thermal half is witness B, batch25); at t = 200 s the recipe closes the feed valve (P2, 'setParameter u = 0' – the whole remaining feed commitment retires as a ledgered feedAmendment record) and drops the outlet boundary (P1, 'setParameter P_out' 1.0 → 0.5 bar); the bed drains through the SAME Ergun face machinery every run already uses; the vented gas rides the telescopic M_out ledger rows.

THE ANCHORS (ideal-gas exactness, hand-computable):

n_end / n_0 = P_end / P_0 = 0.5 n(P) = eps A L P / (R T) = 0.0807 mol at 1 bar, 0.0403 at 0.5 bar vented = inventory drop (the mass-closure KPI is the proof)

The gate (check_pswing) recomputes both analytically and pins the 'gasInventory_mol' KPI + the closure against them.

batch24_tsa_until_css

tutorials/batch/adsorber/batch24_tsa_until_css

What it does: Toward A6: three hand-declared TSA cycles (cold load / 400 K purge) in one campaign – eleven ledgered feed amendments, balances closed, final KPIs at the cycle boundary; the CSS verdict machinery stays a named proposal

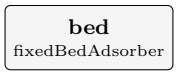
The story: A6 item 4: the cyclic steady state as the STOPPING CONDITION, not a count.

batch23 beside this one declares ‘repeat 3;‘ and reports honestly that three cycles did not settle – it makes the question visible and does not answer it. This case asks what an engineer actually wants to ask of a TSA bed: not "run three cycles" but "cycle until it repeats, and tell me how many that took".

cycle { period 7200; repeat untilCSS; cssTolerance 3e-2; maxCycles 6; ... }

The declared cap is SIX and the run uses TWO, announcing why it stopped.

TWO KEYS ARE MANDATORY under ‘untilCSS‘ and the engine refuses without either: the tolerance, because whether a bed has converged is a modelling judgement the engine must never invent; and the cap, because a bed that never settles has to stop somewhere and the run must be able to say it stopped for want of cycles rather than because it arrived. Reaching the cap is NOT an error – the trajectory is a physically valid campaign and every other KPI in it is real – but it means the case’s own question went unanswered, so it is published (‘css_stopped_at_cap‘) and announced.



WHAT BUILDING IT FOUND, and it outlives the feature: the CSS norm and the loading are NOT the same quantity. See the measured numbers beside ‘cssTolerance‘ below. A tolerance chosen without looking can certify a bed whose loading is still visibly marching, because the norm over the whole packed state is dominated by its largest components. The verdict is only as meaningful as the number the case declares – which is the argument for the engine refusing to supply one.

batch25_blowdown_thermal

tutorials/batch/adsorber/batch25_blowdown_thermal

What it does: P-swing witness B: adiabatic blowdown COOLS (expansion work)

The story: P-SWING WITNESS B: the cooling.

The THERMAL half of a blowdown, isolated from adsorption so the only heat effect in frame is the expansion work itself (design note fixed-bed-thermal-a5.md, section 8/9 amended battery):

same inert pure-He ergun bed as witness A (batch24), but 'energyBalance adiabatic;' – each cell's internal energy U_j = eps c (h - RT) + rho_b cp_s (T - T0) is balanced in conservative finite-volume form (design note section 10); at t = 200 s the recipe closes the feed valve (P2) and halves the outlet boundary (P1) – the bed drains, and the gas that stays behind did the work of pushing the vented gas out: read through the chain rule, the eps R T dc_tot/dt term pulls T DOWN; the solid heat capacity is a declared SYNTHETIC LOW value (9.2 J/(kg K), scope says so): the real ~920 of a zeolite pellet would thermally bury the gas-phase cooling under the solid's mass (dT ~ -0.03 K); at the teaching value the drop is visible (~ -3 K class). Same honest-teaching-value discipline as the hxFluid of the pinch witness – the physics on display is the GAS's, and the header says which knob made it visible.

THE ANCHOR: T_min_final_K sits BELOW the declared 298.15 K by a visible margin – a depressurising cell COOLS, which is exactly what the pre-widening cp-form could not show (the sabotage of the gate restores that form and this witness fails). The material anchors stay witness A's business; this case pins the sign and visibility of the thermal effect. AND ITS FIRST LAW: the campaign energy balance is claimed and closes to round-off (energy_closure_rel ~ 4e-10 of the 2.3 J the blowdown moves, against ~200 J of gross hold-up energy), because the face enthalpy fluxes are shared by the two cells of each face and the vented gas leaves carrying exactly what crossed the outlet face. Until 2026-11-09 the bed carried a temperature form that missed this first law by 7.9 % of the energy moved, at every step size, and the engine refused the claim by name (DEV.md 4c C258).

combustion

The theory you need. Radical chain chemistry: initiation creates the first radicals (slow – $H_2 + M$, $E_a \sim 105\,\text{kcal}$), branching multiplies them ($H + O_2 \rightarrow O + OH$: one in, two out), termination removes them. Ignition is the race between branching and termination; the induction time is set by the SLOW build-up, then heat release runs away. Rate constants $k = AT^b e^{-E_a/RT}$ come VERBATIM from cited papers (Ó Conaire 2004, Glarborg 2018) in their native units – the engine converts and announces. Reverse rates from equilibrium: the kinetic end-state must land on the Gibbs equilibrium (the two-engine handshake the NOx tutorial pins at 99.99 %). Expect stiffness ratios of 10^6–10^8 (use Rosenbrock23), ignition delays in μs validated against shock-tube data, and thermal NO forming over SECONDS – the timescale gap behind quench-based NOx control. *Full derivation: Theory Guide, the combustion/kinetics chapter.*

ignition01_h2o2

tutorials/batch/combustion/ignition01_h2o2

What it does: Adiabatic constant-V H2/O2 ignition at 1100 K (O Conaire 2004 H2/O2 kinetics, NASA-9 thermo); Rosenbrock23 stiff solver; reports ignition delay

The story: closed rigid vessel, stoichiometric H2/O2 in N2 at 1100 K.

H2 : O2 : N2 = 2 : 1 : 4 (stoichiometric H2 + 1/2 O2 → H2O, 57% N2)

mode adiabatic + energy gasConstantV: the first law dU = 0 in a fixed volume, with the heat release coming from the species FORMATION enthalpies (curated thermo) – no per-reaction ΔH is supplied. Temperature, and the radicals H/O/OH/HO2, are integrated by the stiff solver until branching runs away.

solver { integrator Rosenbrock23; } – the L-stable stiff method. Swap to RK4 (see the ignition01_h2o2_rk4 sibling) and the same step blows up.

A closed rigid vessel holds a stoichiometric H_2/O_2 charge diluted in N_2 at 1100 K and 5 bar. A trace H-radical seed starts chain branching; after a short induction the radical pool explodes and the mixture ignites — a sharp temperature jump from 1100 K to ~3078 K.

and plot trajectory.csv (T and the radicals H/O/OH vs time). You will see:

The ignition delay τ_ign (the time of maximum dT/dt, printed in the run's epilogue on the 1 μs write grid) is ≈ 8 μs here. The trace H seed is what makes it that short: the same mechanism without a seed, at 2 atm, gives the 43 μs of the shock-tube pin in ignition02_h2air_slack.

The radical lifetimes are far shorter than the induction — the solver prints a stiffness ratio of order 10?. That is stiffness. An explicit method (RK4) is stability-limited to a step of order the ∗fastest∗ scale, so it cannot take the 1 μs steps this case uses. The solver here is Rosenbrock23, an L-stable linearly-implicit method that steps by ∗accuracy∗, not stability; at verbosity 3 it prints its stiffness verdict and step counts (the no-silent- crutch credo).

See it fail on purpose — two siblings run the same problem at the same step with other integrators:

(Both ship a .expect-nonconvergence marker — their whole point is to fail.) ∗See, then decide∗, applied to numerics.

ignition01_h2o2_eulersi

tutorials/batch/combustion/ignition01_h2o2_eulersi

What it does: WITNESS + EXPECTED FAILURE: semi-implicit Euler on the H2/O2 ignition – A-stable but first-order, goes unphysical at this step and the engine refuses by name (see .expect-nonconvergence).

The story: WITNESS for the EulerSI integrator (semi-implicit Euler) – an EXPECTED FAILURE: see .expect-nonconvergence for why first order at this step goes unphysical and how the engine now refuses instead of exiting 0. Registered model no case selected until 2026-08-22 (invariant I8).

The third integrator of the stiffness lesson. The same adiabatic constant-volume H_2/O_2 ignition as [ignition01_h2o2](../ignition01_h2o2/README.md) (Rosenbrock23, converges) and [ignition01_h2o2_rk4](../ignition01_h2o2_ (explicit RK4, blows up), here with semi-implicit Euler (integrator EulerSI;) at the same deltaT = 1e-6 s.

Semi-implicit Euler is A-stable, so it does not oscillate to infinity the way RK4 does — the first steps are physical (T 1100 → 1102 → 1108 → 1139 K) — but it is FIRST ORDER, and once the ignition transient starts one linearised step is wrong enough to drive the state unphysical. The integrator reports that it gave up, and the reactor refuses by name instead of exiting 0:

.expect-nonconvergence records why that refusal exists (until 2026-08-22 this exact run reached a negative temperature and exited 0). L-stable second order converges, explicit fourth order blows up loudly, A-stable first order fails honestly: ∗see, then decide∗, applied to numerics.

Same as the sibling: the ? Conaire et al. (2004) H_2/O_2 mechanism (constant/reactions, shared with ignition02_h2air_slack) and NASA-9 heat capacities from NASA/TP-2002-211556 for H_2, O_2, N_2 and water. Until 2026-10-25 it ran a GRI-Mech 3.0 subset, replaced because GRI-Mech grants no redistribution (DEV.md ?4c C164); the failure it teaches did not change.

ignition01_h2o2_rk4

tutorials/batch/combustion/ignition01_h2o2_rk4

What it does: Adiabatic constant-V H2/O2 ignition at 1100 K (O Conaire 2004 H2/O2 kinetics, NASA-9 thermo); EXPLICIT RK4 – fails on the stiff chemistry (the lesson)

The story: ignition01_h2o2 – closed rigid vessel, stoichiometric H2/O2 in N2 at 1100 K.

H2 : O2 : N2 = 2 : 1 : 4 (stoichiometric H2 + 1/2 O2 → H2O, 57% N2)

mode adiabatic + energy gasConstantV: the first law dU = 0 in a fixed volume, with the heat release coming from the species FORMATION enthalpies (curated thermo) – no per-reaction ΔH is supplied. Temperature, and the radicals H/O/OH/HO2, are integrated by the stiff solver until branching runs away.

solver { integrator Rosenbrock23; } – the L-stable stiff method. Swap to RK4 (see the ignition01_h2o2_rk4 sibling) and the same step blows up.

This is the failure half of the stiffness lesson. It runs the exact same adiabatic constant-volume H_2/O_2 ignition as the sibling case [ignition01_h2o2](../ignition01_h2o2/README.md), but with the explicit RK4 integrator instead of the stiff Rosenbrock23 — at the same fixed step (deltaT = 1e-6 s).

The first step is still plausible (T 1100 → 1110 K); the second already throws the state out of the physical region (T near 8000 K, H_2 at zero), and the third is nan. The engine refuses rather than exit 0:

That blow-up is the result. The stiff sibling prints a stiffness ratio of order 10? for this chemistry: an explicit method is stability-limited to a step of order the ∗fastest∗ scale, so a step chosen for the ∗induction∗ is murdered by stability long before accuracy matters.

Compare side-by-side with ignition01_h2o2, whose L-stable adaptive sub-stepping integrates the ∗same∗ chemistry to a clean burned state (~3078 K), and with ignition01_h2o2_eulersi, which is A-stable but first order and fails honestly by name. ∗See, then decide∗, applied to numerics.

This case ships a .expect-nonconvergence marker, so bin/runTests counts it as an EXPECTED-FAIL — its whole point is to fail.

Same as the sibling: the ? Conaire et al. (2004) H_2/O_2 mechanism (constant/reactions, shared with ignition02_h2air_slack) and NASA-9 heat capacities from NASA/TP-2002-211556 for H_2, O_2, N_2 and water. Until 2026-10-25 it ran a GRI-Mech 3.0 subset, replaced because GRI-Mech grants no redistribution (DEV.md ?4c C164); the failure it teaches did not change.

ignition02_h2air_slack

tutorials/batch/combustion/ignition02_h2air_slack

What it does: Stoich H2/air ignition, 1100 K / 2 atm (Slack shock tube; O Conaire 2004 kinetics)

The story: / flowsheetDict Stoichiometric H2/air autoignition at 1100 K / 2 atm against the Slack shock-tube point (O Conaire 2004 kinetics): the radical pool (H, O, OH, HO2) builds exponentially through the induction time, then runaway. A stiff-integrator showcase – compare the ignition delay with the measured shock-tube value.

Stoichiometric H_2/air, 1100 K, 2 atm, constant volume — the reflected-shock condition of Slack (1977) as compiled in ? Conaire et al. 2004 (Fig 8). Kinetics: the ? Conaire H_2/O_2 mechanism, Table I verbatim (19 reactions; two Troe falloffs; two summed pairs; A in cm^3-mol-s, Ea in kcal — the engine converts and announces every one).

Result: τ_ign (max dT/dt) = 43 μs vs the measured ~40–60 μs window.

Two lessons: 1. No seed. This mechanism self-initiates, and the 43 μs delay is the chain-BRANCHING chemistry (R1-R3), not the dissociation R5 ($H_2 + M = 2H$, Ea = 105 kcal/mol): MEASURED 2026-10-31, when R5-R8 first ran at their true rate (DEV.md 4c C185 item 9 – they had run at ZERO), the delay stayed 43 μs, and removing R5 from the mechanism leaves it at 43 μs too. (This paragraph used to credit R5 with the induction; that was written while R5 ran at zero and was never true.) With the ignition01-style trace-H seed the delay collapses to 12 μs: initial conditions are physics, not knobs. 2. The engine now prints tau_ign in the epilogue (time of max dT/dt on the write grid) whenever a vessel ignites — no CSV spelunking.

Run ignition01_h2o2 (the same kinetics, 5 bar, trace-H seeded) for the sibling case and the stiffness lesson (_rk4).

nox01_zeldovich_postflame

tutorials/batch/combustion/nox01_zeldovich_postflame

What it does: Thermal NOx in post-flame H2/air gas, 2125 K / 1 atm (Glarborg 2018 N chemistry)

The story: / flowsheetDict Thermal NOx in post-flame H2/air gas at 2125 K / 1 atm: the Zeldovich N-chemistry (Glarborg 2018 rate set) integrated in a batch reactor – NO grows on the SECONDS scale while the O/H radical pool stays equilibrated, the classic separation of scales that makes thermal NOx a post-flame problem.

Hot burnt gas (lean H_2/air, 2125 K, 1 atm — Homer & Sutton Flame 1 as compiled in Glarborg 2018) held isothermal, starting from the equilibrated H/O radical pool with all nitrogen still as N_2. The Glarborg 2018 nitrogen chemistry (extended Zeldovich + N_2O routes, Tables 2/5 verbatim) then forms NO.

What is not carried. Glarborg's NNH route (R20–R24) is absent since 2026-10-25: NNH's thermo had come from GRI-Mech 3.0's thermo file, which grants no redistribution, and no public-domain primary for it was found (NASA/TP-2002-211556 has no NNH entry). The heat capacities of the flame species are NASA-9 polynomials from that report. On 2026-07-02, with the NNH route and the earlier thermo, the same table read 5227 / 5167 ppm (98.9 %), 0.50 s and 1.56 s.

1. The cross-engine pin. The kinetic plateau lands on the Gibbs equilibrium computed by a ∗different engine∗ (steady Gibbs minimisation vs stiff batch integration). Kinetics choose the path and the clock; the destination belongs to the thermodynamics. Reverse rates come from the same equilibrium constants — so this agreement is a genuine consistency check of the mechanism transcription + thermo, not a tautology. 2. NOx forms in engineering time. Ignition takes microseconds (ignition02: 43 µs); thermal NO takes seconds at 2125 K. That timescale gap is the whole basis of NOx control by quench: cool the gas before the Zeldovich clock runs.

The burnt-gas initial pool was computed by a gibbsReactor at 2125 K/1 atm (14 species on 2026-07-02; it still agrees with the current 13-species thermo to the printed digits) (25 % H_2 / 17.5 % O_2 / 57.5 % N_2 feed); the equilibrium NO share was returned to N_2/O_2 elementally.

crystallisation

The theory you need. Crystallisation removes solute when the solution crosses saturation: $m > m_{\mathrm{sat}}(T)$, with $K_{\mathrm{sp}}(T)$ from ΔG_{diss} and its T-dependence from ΔH_{diss} (van 't Hoff). The heat of crystallisation is ION-DERIVED – $\Delta H_{\mathrm{cryst}} = -(\Delta H^{\infty}_{\mathrm{soln}} + \bar{L}_2(m_{\mathrm{sat}}))$ – never a stored constant (a solid's formation enthalpy is $\sum \nu_i h^{\mathrm{aq}}_{f,i} - \Delta H_{\mathrm{soln}}$, derived, single-sourced). Antisolvent cases add the mixed-solvent electrolyte model (eNRTL): ethanol drops the dielectric constant, $\gamma_{\pm}$ rises, salt crashes out. Expect supersaturation as the driving force and yields set by the solubility curve, not the kinetics (these cases are equilibrium-staged). *Full derivation: Theory Guide, the crystallisation + electrolyte-enthalpy chapters.*

batch13_nacl_pitzer

tutorials/batch/crystallisation/batch13_nacl_pitzer

What it does: Batch NaCl crystalliser: saturation from the Pitzer ion activity, not a solubility curve

The story: One closed vessel. The unit declares no saturation of its own: it asks the thermodynamics the case declares, and the case declares Pitzer.

What to expect (golden-locked):

drying

dryer01_sucrose_tray

tutorials/batch/drying/dryer01_sucrose_tray

What it does: Tray drying of wet sucrose into declared 60 C air: the classical constant-rate / falling-rate drying curve, with the wet bulb and the GAB equilibrium moisture as results

The story: the DRYING CURVE, both periods, in one batch.

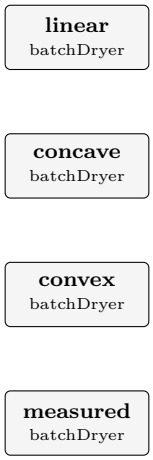
A tray holding 2.0 kg of dry sucrose wet to X_0 = 0.30 kg water / kg dry solid, exposed over 0.5 m2 to air of DECLARED, CONSTANT condition: 60 C (333.15 K) and Y = 0.010 kg water / kg dry N2. Nothing about that air is integrated – it is an ENVIRONMENT, the FixedBedAdsorber's constant-carrier posture, and the water that leaves the solid leaves the campaign across that boundary (reported as the unit's DECLARED material residual, never as a silent leak).

THE HAND ESTIMATE, computed from this case's own curated records (water Antoine + Watson Hvap + the two ideal-gas Cp polynomials, the case-local GAB isotherm on sucrose) – the run must reproduce it:

air water activity p_v = P Y/(Y + Mv/Mc) = 1551 Pa a_w = p_v / Psat(333.15 K) = 0.0774 GAB equilibrium K a_w = 0.0743 X_eq = Xm C Ka /((1-Ka)(1-Ka+C Ka)) = 0.01580 kg/kg wet bulb (Lewis = 1) T_wb = 300.53 K (27.4 C, a 32.6 K depression) driving force Y_sat(T_wb) - Y = 0.014011 kg/kg constant-rate flux R_c = k_Y dY = 0.05 ∗ 0.014011 = 7.0057e-4 kg/(m2 s) R_c A = 3.5028e-4 kg/s latent load R_c A lambda(T_wb) = 0.8645 kW (the AIR's, not the campaign's – KPI only, never ledgered) break time t_c = m_s (X_0 - X_c)/(R_c A) = 1027.7 s falling-rate constant tau = m_s (X_c - X_eq)/(R_c A) = 595.0 s end of run X(3000 s) = X_eq + (X_c - X_eq) exp(-(3000-t_c)/tau) = 0.019584 kg/kg

What to look at in the output: trajectory.csv columns dryer.X_kg_kg and dryer.R_kg_m2_s: the drying curve and the rate curve, engine columns, not a post-processing. R is FLAT at 7.0057e-4 until X falls through X_c = 0.12, then decays linearly in (X - X_eq) – the textbook break, visible as a corner. The falling rate is DECLARED as the characteristic drying curve f = Phi^n with n = 1, which IS the linear law; the drying EduTool varies n (n < 1 reaches X_eq in finite time, n > 1 an algebraic tail slower than the exponential), and dryer02_characteristic_curves runs four shapes side by side. the KPI t_critical is OBSERVED (the interpolated crossing between two accepted states), not the analytic 1027.7 s above; they agree because dX/dt is exactly constant on that leg. THE CAMPAIGN MASS BALANCE CLOSES BECAUSE THE DRIED WATER IS AN OUTLET. The solid is charged with 2.600000 kg and ends with 2.039168 kg; the 0.560832 kg of difference is the DRIED WATER. It left the solid and went into the air, and the campaign books it as an external OUTLET STREAM of the dryer (the ledger record 'dryer → (external boundary)', "evaporated water leaving the solid into the drying air"): initial = final + external out, mass and element closure at round-off. The air stays a DECLARED ENVIRONMENT (a temperature and a humidity, not a vessel this campaign owns), but matter crossing the campaign boundary is a stream whatever receives it. Until 2026-11-09 this unit left the water off the books and the balance read a 21.6 % shortfall that only the log explained; a violated balance on screen is a defect, so it is a stream now (DEV.md 4c C258).

the campaign energy balance is UNAVAILABLE, and says why in one sentence: the drying heat comes from air this campaign never owned. The number is not hidden – it is the latentDuty_kW KPI.



Method hypotheses, each announced at run time: Lewis = 1 in the adiabatic-saturation equation; the humid heat evaluated at the air's own temperature; the surface held at T_wb while X > X_c; the LINEAR falling-rate curve (n = 1; a modelling CHOICE, not physics, and its declared source says so); the solid's own temperature NOT integrated.

dryer02_characteristic_curves

tutorials/batch/drying/dryer02_characteristic_curves

What it does: The characteristic drying curve: one wet sucrose tray, one declared air, four falling-rate shapes – linear, Phi^0.5, Phi^2 and a table

The story: THE CHARACTERISTIC DRYING CURVE.

Four identical trays of dryer01 (2.0 kg dry sucrose at X_0 = 0.30, 0.5 m2, air at 60 C and Y = 0.010, X_c = 0.12) that differ in ONE thing: the shape of the falling-rate period. van Meel (Chem. Eng. Sci. 9 (1958) 36-44) observed that for many materials the drying rate normalised by the constant rate is a single function of the normalised free moisture,

Phi = (X - X_eq)/(X_c - X_eq), f = R/R_c = f(Phi), f(1) = 1, f(0) = 0,

so ONE measured curve describes the material at any air condition – the air sets R_c (the wet bulb) and X_eq (the isotherm), the curve sets the rest. The shape is the material's, MEASURED; each tray declares one (src/unitOperations/heatTransfer/DryingCurve.H):

linear f = Phi the textbook tail, dryer01's law, declared concave f = Phi^0.5 rate held high: reaches X_eq in FINITE time, t' = tau/(1 - n) = 2 tau convex f = Phi^2 rate dropping early: an algebraic tail, Phi = 1/(1 + t'/tau), slower than linear measured a (Phi, f) table S-shaped, interpolated linearly

tau = m_s (X_c - X_eq)/(R_c A) = 595.0 s (dryer01's hand estimate) is the SAME for all four – the constant-rate period, t_c = 1027.7 s, too. What differs is only the falling period, and the end-of-run moisture, at t' = 3000 - 1027.7 = 1972.3 s into it:

linear X = X_eq + (X_c - X_eq) exp(-t'/tau) = 0.019584 (= dryer01) convex X = X_eq + (X_c - X_eq)/(1 + t'/tau) = 0.03995 concave X = X_eq = 0.015798, reached at t' = 2 tau = 1190 s – the engine lands 3.8e-8 kg/kg BELOW it (2.4e-6 relative): RK4 stepping onto a point where f = Phi^0.5 has an infinite slope, the size (dt/tau)^2 (X_c - X_eq)/4 predicts. Not clamped (no clamp in this unit, by rule); it shrinks with dt. measured 0.03502 (no closed form), between linear and convex, as its points lie below the linear curve bin/curate/check_drying_curve.py recomputes all of this from the run.

EVERY CURVE HERE IS HYPOTHETICAL. No measured characteristic curve of sucrose is in this repository; the shapes are chosen to span what materials do, and each tray says so in its 'source'. A real design reads its curve from a thin-layer drying test of ITS material.

electrodialysis

edbatch01_constant_current

tutorials/batch/electrodialysis/edbatch01_constant_current

What it does: Batch recirculating electrodialysis at constant current: the limiting current falls with the depleting diluate until i crosses it

The story: a batch electrodialysis rig run at CONSTANT CURRENT, and the limiting current falling under it until they cross.

THE OPERATION. Five litres of 0.1 mol/kg brine in the diluate tank, five litres of 0.5 mol/kg in the concentrate tank, both recirculated through the bench stack of 'ed03_stack_record' (Eurodia EUR2C-7P18, seven cell pairs, 0.020 m2 each) at the paper's own 175 L/h. The rectifier is held at 3.5 A, which is 175 A/m2 on one cell pair.

WHY IT IS A DIFFERENT EXPERIMENT FROM ed01-ed05. Those are steady: one pass, a fixed diluate composition, so the limiting current is evaluated ONCE. Here the diluate tank DEPLETES, and i_lim – which the GeraldesAfonso2010 model predicts from the ion diffusivities and the diluate composition – falls with it, while i does not move at all. They must cross.

WHAT THE RUN MEASURES (every number below is printed by this run; nothing here is a target):

i 175.00 A/m2, flat, all 2000 s i_lim 643.04 A/m2 at t = 0 88.26 A/m2 at t = 2000 s THE CROSSING t = 1593 s (i/i_lim reaches 1) i/i_lim at the end 1.983 xi_eff 0.900 → 0.4539 (the plateau, below) demineralisation 86.27 % ACTUAL 91.41 % what the hand calculation predicts the hand calculation's own answer: the tank is EMPTY at t = 2188 s concentrate 0.5 → 0.5863 mol/kg (x1.173) specific energy 1.946 kWh per m3 of diluate treated material closure 1.4e-15 on mass, 8.5e-14 on the worst element

THE LESSON. Faraday's law at constant current is a STRAIGHT LINE:

n(t) = n(0) - xi I N t / (z F)

and it is what a student computes by hand. The run publishes it as 'demin_ideal', evaluated from THIS run's own initial current, own initial inventory and own declared xi – computed, never declared, so the gap cannot have been arranged – beside 'demin_actual'.

The two agree exactly until t = 1593 s and part after it, and the reason is printed at the instant it happens: i has caught i_lim. At the limiting current the counter-ion concentration vanishes at the diluate/membrane interface and the film can deliver no more of it, so a larger current is carried by water-splitting products instead of by salt. This case DECLARES that model – 'overLimiting { model saltFluxPlateau; }', xi_eff = xi i_lim/i, which adds no parameter – so the depletion stops being linear and becomes asymptotic: the straight line hits zero at 2188 s and the tank never does.

WITHOUT the declaration (the default) the current efficiency would stay at xi and the two curves would coincide to the integrator's own precision. That is not a better answer; it is a model with nothing in it that could part from the hand calculation, and the run SAYS so when i crosses i_lim. 'edbatch02_constant_voltage' is the same rig with the rectifier held at a voltage instead: there the current DECAYS, the crossing never happens, and the same hand calculation fails for an entirely different reason.

WHAT IS PINNED AND WHAT IS NOT. The golden pins the answer THIS model gives. Nothing here is validated against a measured batch electrodialysis: the stack record reproduces the paper's bench unit and its limiting-current correlation, but no run of that unit in recirculating batch is transcribed anywhere in this tree. 't_overLimiting_s' is resolved to the TIME STEP – it is the first accepted step at which i exceeds i_lim, so it moves with deltaT (1593 s at deltaT 1, 1592.5 s at deltaT 0.25) while everything else is converged to ~1e-8.

NOT MODELLED, and it matters to how far this run can be trusted: no salt diffuses back from the concentrate, no water is transported with the ions, the current efficiency is a declared constant apart from the plateau above, and the rig is isothermal with the Joule heat removed by no modelled duty (which is why the campaign energy balance reports UNAVAILABLE and says why). The full list is in the unit's own header.

edbatch02_constant_voltage

tutorials/batch/electrodialysis/edbatch02_constant_voltage

What it does: Batch recirculating electrodialysis at constant voltage: the current decays as the diluate loses conductivity, and never reaches the limiting current

The story: THE SAME RIG, one knob different, and the hand calculation failing for the opposite reason.

Everything is identical to ‘edbatch01_constant_current‘ – the same stack, the same two tanks, the same recirculation flow, the same xi, the same electrode term – except that the rectifier is held at 4 V instead of 3.5 A. The difference between the two runs IS the difference between the two ways of driving a batch electrodialysis.

WHAT THE RUN MEASURES (printed by this run; nothing here is a target):

I 4.365 A at t = 0 → 2.018 A at t = 1500 s i/i_lim 0.3394 → 0.4086 NEVER reaches 1 demineralisation 61.59 % ACTUAL 85.51 % what the hand calculation predicts the hand calculation’s own answer: the tank is EMPTY at t = 1754 s diluate 0.1 → 0.03841 mol/kg kappa (diluate) 1.262 → 0.4846 S/m E_mem (per pair) 0.0794 → 0.1313 V specific energy 1.048 kWh per m3 of diluate treated material closure machine level, as in edbatch01

WHY THE CURRENT FALLS. The stack equation is

U = N (E_mem + I R_pair) + E_electrodes

and BOTH terms inside the bracket move against the current as the run proceeds. The diluate loses conductivity, so R_pair rises (0.0636 → 0.1119 Ohm per cell pair); and the concentration RATIO between the two tanks grows, so the Nernst back-EMF rises with it. At fixed U the current has nowhere to go but down, and it more than halves.

WHY IT NEVER CROSSES i_lim. i_lim falls as the diluate depletes – exactly as in edbatch01 – but so does i, and here they fall together: the ratio ends at 0.409 having started at 0.339. That is the reason a real bench rig is run this way when the membranes matter: constant voltage is self-limiting, and the price is time. This case declares NO ‘overLimiting {}‘ model at all, and the run announces that default; it is irrelevant here precisely because the crossing never happens.

THE LESSON, and it is the same lesson as edbatch01 arriving by a different road. ‘demin_ideal‘ is Faraday’s law at the INITIAL current – a straight line, computed from this run’s own I(0), own inventory and own xi. It is 24 percentage points optimistic at 1500 s, and not one of those points has anything to do with the limiting current: the current simply is not what it was. Read ‘I_A‘ in trajectory.csv beside ‘deminActual‘ and ‘deminIdeal‘ and the whole of the gap is in that first column.

WHAT IS PINNED AND WHAT IS NOT: as edbatch01. The golden pins the answer this model gives; no measured batch electrodialysis is reproduced anywhere in this tree.

edbatch03_multiionic_split

tutorials/batch/electrodialysis/edbatch03_multiionic_split

What it does: Batch electrodialysis of a mixed NaCl + K2SO4 brine: two counter-ions on each membrane share its current by z D c

The story: a batch electrodialysis rig on a MIXED brine, and two counter-ions on each membrane sharing its current.

THE OPERATION. The rig of edbatch01 (Eurodia EUR2C-7P18, seven cell pairs, 175 L/h recirculation), but the diluate tank holds 0.05 mol/kg NaCl plus 0.025 mol/kg K2SO4 – two cations (Na+, K+) on the cation-exchange membrane and two anions (Cl-, SO4 2-) on the anion-exchange one. The rectifier is held at 2.0 A (100 A/m2 on one cell pair).

THE RULE (Vitor's ruling C35, 2026-10-05). Until that day this unit REFUSED a diluate with more than one cation or one anion, for want of a rule dividing a membrane's current between its counter-ions. The ruling shares it by

t_k = |z_k| D_k c_k / SUM_j |z_j| D_j c_j over that membrane's counter-ions

– the transport numbers of Geraldes & Afonso, J. Membr. Sci. 360 (2010) 499-508, Eqs. (12)/(13), applied at every current and not only at the limit – with D the ions' curated D0 and NO new parameter. Each ion then leaves at t_k xi I N / (|z_k| F) mol/s, so each membrane moves exactly xi I N / F equivalents and both tanks stay electroneutral.

WHAT A STUDENT SHOULD SEE. Divide that rate by the ion's own inventory:

d ln n_k / dt = - D_k xi I N / (F SUM_j |z_j| D_j n_j)

– the FRACTIONAL depletion rate of a counter-ion is proportional to its diffusivity and to nothing else about it, so on a log scale the counter-ions of one membrane fall along straight lines whose slopes stand in the ratio of their D0. K+ (1.96e-9 m2/s) is depleted 1.47 times faster than Na+ (1.33e-9) in log terms; Cl- (2.03e-9) 1.92 times faster than SO4 2- (1.06e-9), the charge of the sulfate making no difference to its FRACTIONAL rate (it carries twice the current per mole and so moves half the moles per coulomb, exactly compensating its doubled share). The run publishes 'demin_<ion>' for every ion and 't_transfer_final_<ion>', the shares at the end, and its trajectory carries every molality.

WHAT THE RUN MEASURES (every number is printed by this run; the golden pins them): i 100.00 A/m2, flat, all 2400 s i_lim 696.83 A/m2 at t = 0, 244.39 at t = 2400 s (i/i_lim 0.144 → 0.409: never crossed) removed at t = 2400 s K+ 69.77 % Na+ 55.60 % (CEM) Cl- 74.43 % SO4 2- 50.94 % (AEM) share of the current Na+ 0.404 → 0.499 of the CEM's Cl- 0.657 → 0.500 of the AEM's material closure 0 on mass, 1.4e-15 on the worst element

READ THE SHARES BACKWARDS AND THE LESSON IS THERE. At t = 0 the two cations are equally concentrated, so K+, the faster, takes 0.596 of the cation current; it therefore depletes faster, its c falls, and the share drifts toward Na+. The hand calculation 'demin_ideal' (Faraday's law at the INITIAL current AND the reference cation's INITIAL share, computed from the run) predicts 50.68 % of the sodium removed; the run removes 55.60 %, because sodium's share of the current GROWS as potassium is stripped – the opposite sign from edbatch01's gap, and for a different reason. And ln(n/n0)/D0 comes out as one number for K+ and Na+, and one number for Cl- and SO4 2-, to the integrator's precision.

WHAT IS PINNED AND WHAT IS NOT. The golden pins the answer THIS model gives. The share z D c is a RULING, not a measurement: real ion-exchange membranes add a preference between counter-ions of their own (a Donnan preference for divalent ions, or a monovalent-selective layer) which no 'kind IEM' record in this tree carries and this unit does not model. The brine is an author-set assumption; nothing here is validated against a measured rig. The membrane potential of a membrane with two counter-ions is taken as the MEAN of their own Nernst potentials (announced). Back- diffusion, water transport and every thermal effect are not modelled – the unit's own header lists them.

membrane

diafilter01_nf_desalting

tutorials/batch/membrane/diafilter01_nf_desalting

What it does: Constant-volume NF diafiltration: NaCl washed out of an MgSO4 retentate, with the OBSERVED rejection published beside the constant-R washout law it violates

The story: constant-volume diafiltration on a loose NF membrane, and the exponential washout law failing in a way you can watch.

THE OPERATION. 10 litres of a brine carrying TWO salts sit behind 5 m2 of NF270 at 10 bar. Solvent is made up as fast as it permeates, so the volume is held and the run is measured in DIAVOLUMES – how many vessel volumes of wash water have passed through. NaCl is poorly rejected by this membrane and leaves; MgSO4 is well rejected and stays. That is the whole point of a nanofiltration desalting step, and it is the same arithmetic whether the retained species is a divalent salt, a sugar or a protein.

THE LESSON. Derive the washout by hand. Over a constant volume V, with the permeate carrying c_p = (1 - R) c,

V dc/dt = -Q_p (1 - R) c , N = Q_p t / V => c/c_0 = exp(-(1 - R) N)

which is a straight line on a log axis against N. The derivation needs R to be CONSTANT. It is not:

as NaCl leaves, the osmotic pressure of the retentate falls, so the driving force rises and so does the water flux; a higher flux sweeps more solute to the wall, so the polarisation factor rises and the WALL concentration is no longer the bulk one; the observed rejection is measured against the bulk, so it moves even when the membrane's own permeability has not changed.

The run therefore publishes R_obs for each solute at every instant, beside the diavolumes, and – because this is constant-volume mode – two KPIs per solute: 'washoutActual_<name>' (what the vessel did) and 'washoutIdeal_<name>' (what exp(-(1-R)N) predicts using THIS run's own initial R). The idealisation is computed from the run, not declared, so the gap between them cannot have been arranged.

Read them together. Where the two agree, the hand derivation was safe. Where they part, the R_obs column says which assumption failed and when.

WHAT IS PINNED AND WHAT IS NOT. The golden pins the answer this model gives; NOTHING here is validated against a measured diafiltration. The NF270 permeabilities are the case-fitted pedagogical set the record declares ('provenance fittedToCase', fitted against membrane02_NF_sugar), so the rejections are representative of a loose NF membrane and are not a claim about a particular element. Fouling is NOT modelled – the flux in a real rig would decline with time and this one does not.

diafilter02_fouling_decline

tutorials/batch/membrane/diafilter02_fouling_decline

What it does: The same diafiltration with a DECLARED Hermia cake-law decline: what fouling costs a washout schedule

The story: the same diafiltration, with the membrane losing permeance as it works.

WHY THIS CASE EXISTS. diafilter01's flux RISES during the run (233 → 256 LMH): the salt leaves, the osmotic pressure falls, the driving force grows. That is the physics the model has. It is not what a rig does. On real equipment the flux falls, because the membrane fouls, and every schedule a student will ever write is sized on that decline.

THE MODEL. Resistance in series on the permeance the unit hands the transport law:

1 / A_eff = 1 / A_w + r_f(v), v = V_permeated / A

with r_f growing by one of HERMIA'S BLOCKING LAWS (Hermia, Trans. IChemE 60:183-187, 1982). Here 'cake': r_f = k v, the deposited-layer form. Applied where the transport CONTEXT is assembled, so solution-diffusion and DSPM-DE are served alike and neither is modified.

THE CONSTANT IN THIS CASE IS HYPOTHETICAL AND IS NOT A FITTED VALUE FOR THIS SYSTEM. ∗∗ A brine of NaCl and MgSO4 is fully dissolved; there is no suspended matter to deposit, so 'cake' is not a mechanism this feed can honestly claim. What this case demonstrates is the CONSEQUENCE of a declared decline on a diafiltration schedule – how many more minutes the same washout costs – on a system whose other numbers are already pinned by diafilter01, so the difference between the two runs is the fouling and nothing else. It is a STRUCTURAL witness, in the same sense as edwards01_sour_water_activity: no number in it is validated against a measured fouling experiment, and the tree carries no fouling data at all.

A fouling constant belongs to a RIG AND A MATERIAL, not to a membrane, so it is declared here in the case and no catalogue record is touched.

WHAT TO READ. 'A_eff_over_A_w' in the trajectory is the permeance the membrane still has, as a fraction of clean. Put diafilter01 and diafilter02 side by side: same charge, same area, same pressure, and the diavolume count at t = 160 s is the whole lesson.

diafilter03_dspmde_batch

tutorials/batch/membrane/diafilter03_dspmde_batch

What it does: Batch NF concentration on the DSPM-DE pore model: the observed rejection per instant and the campaign's time-averaged rejection

The story: batch CONCENTRATION of a two-salt brine on the DSPM-DE pore model, and the rejection of a whole campaign stated as a TIME average.

THE OPERATION. The charge of diafilter01 (10 litres, 0.02 kmol/m3 each of NaCl and MgSO4) sits behind 1 m2 of NF270 at 10 bar with NO make-up solvent, so the vessel shrinks and both salts concentrate. The membrane is the pore tier of the curated NF270 record ('NF270_dspmde': pore radius, A_k/dx, a constant volumetric charge, a pore dielectric constant), and the transport law is DSPM-DE – steric, Donnan and dielectric exclusion with the extended Nernst-Planck equations SOLVED across the pore – asked at every instant of the integration, exactly as the spiral module asks it at every station of its channel. The film is the declared k_film with the default film theory (announced).

WHAT THE RUN SHOWS. The observed rejection is not a property of the membrane alone; it moves with the solution the membrane sees. As the retentate concentrates the NaCl rejection FALLS (0.691 at the start, 0.554 at the end of this run) while the MgSO4 rejection RISES slightly (0.973 → 0.979). In DSPM-DE two things push the monovalent salt the same way – a bulk concentration growing past the fixed charge weakens the Donnan exclusion, and a growing share of retained divalent ions changes what must cross to keep the permeate neutral – and this run does not separate them. The flux falls with the osmotic pressure (244 → 116 LMH) and the volume reduction reaches 3.9. Read 'R_obs_<salt>' in the trajectory against 'V_m3'.

THE REJECTION OF THE CAMPAIGN. A batch rig is usually judged by the permeate it COLLECTED, not by one instant, and two time averages of the rejection are published at the end (DEFINED in BatchDiafilter.cpp, kpis(), and in docs/ai/membrane-research.md).

R_avg = 1 - c_permPooled / c_bMeanPerm, where c_permPooled = (n_0 - n) / V_perm is the pooled permeate (every drop collected, mixed) and c_bMeanPerm = INTEGRAL c_b dV_perm / V_perm is the retentate's bulk concentration averaged over what permeated. It is a weighted mean of the instantaneous R_obs (weights c_b Q_p), so it lies between the smallest and the largest of them (NaCl 0.635).

R_avgVsInitialFeed = 1 - c_permPooled / c_bInitial compares the pooled permeate with the CHARGE and, because the retentate only concentrates, lies below R_avg (NaCl 0.467) – the number a laboratory gets by analysing its collected permeate against the feed it started from, and a reminder that it is not the membrane's rejection. The steady spiral module states the SPATIAL counterpart: its R_obs is the mixed permeate of the whole channel against the inlet feed.

WHAT IS VERIFIED AND WHAT IS NOT. Verified (check_diafiltration): the DSPM-DE pore model runs inside the batch vessel at every instant; matter is conserved to machine precision; the two averages reproduce from the published integrals and from the trajectory; R_avg lies inside the range of R_obs; the pooled-permeate rejection lies below it, as it must when the retentate concentrates. NOT validated: no number here is compared with a measured batch filtration. The pore parameters are the record's case-fitted pedagogical set ('provenance fittedToCase', fitted against membrane10_dspmde_divalent), so the rejections are those of a representative loose NF membrane, not a claim about a particular element. In a MIXED feed the salt basis carries each salt's cation leg through the pore and the run says so; fouling is not declared; k_film is declared, not correlated with a stirrer or a channel.

plant

apalutamide01_tablets

tutorials/batch/plant/apalutamide01_tablets

What it does: APALUTAMIDE 60 mg FILM-COATED TABLETS, a drug-product plant (the API is BOUGHT), a generic entrant at loss of exclusivity, on a SOURCED design basis (docs/design/apalutamide-design-basis-dossier.md): the originator's patent formula (US 12,303,493 B2: a 1:3 apalutamide:HPMCAS-LG dispersion, a 700 mg core, a 3 % Opadry II coat), the dispersion spray-dried from 5 wt % acetone (the patent's acetone example) through a pressure nozzle in a closed nitrogen loop (blower, heater, spray dryer, exhaust cooler, -10 C solvent condenser, purge and N2 make-up), the recovered acetone to a tank for QC; dry granulation (blending, roller compaction, milling, a screen with a fines recycle), final blend, tableting with rejects, film coating (an aqueous coat sprayed on and its water dried off by hot air) and packaging. The steady flowsheet is the material balance per unit of product (15 625 tablets/h pressed, the patent's PSD-3 dryer at 75 kg/h of solution, is a basis); a BATCH PLAN (system/postDict) sizes each step for a 400 kg lot, counts 25 lots a year for 14.0 million tablets (25 % of the estimated European market), and finds the pace of each train – the spray dryer on round-the-clock campaigns, the solid-dose suite lot by lot on two shifts. Blending, compaction, milling, screening, tableting and packaging are MASS-BALANCE PLACEHOLDERS (no equipment physics). Every number the dossier could not source is an author-set assumption, said so where it is declared (README).

The story: a drug-product plant: apalutamide 60 mg film-coated tablets. The API is BOUGHT; everything else is made here (DEV.md 4c C97, phase A). A BASE CASE: it runs, it is NOT optimised, and every number a group would change is a plain key, said to be an assumption where it is declared. The README is the narrative; this file is the topology.

THE BASIS (README section 2; the design-basis dossier, docs/design/apalutamide-design-basis-dossier.md): 15 625 tablets per hour PRESSED, the flowsheet basis, of the originator's patent formula (US 12,303,493 B2, Examples 3.1-3.3): a 700 mg core carrying 60 mg of apalutamide in 240 mg of a 1:3 apalutamide:HPMCAS-LG spray-dried dispersion, with a 21 mg (3.0 %) film coat. 15 625 tablets/h is the patent's PSD-3 dryer at its 75 kg/h of 5 wt % solution (3.75 kg/h of dispersion / 240 mg). THIS STEADY FLOWSHEET IS THE MATERIAL BALANCE PER UNIT OF PRODUCT (DEV.md 4c C99): the plant runs in BATCHES (lots of final blend, released one by one) and its spray dryer in CAMPAIGNS, and the BATCH PLAN in system/postDict sizes each step for one lot from these streams' masses, counts the lots a year from the declared production, and finds the step that paces each train. The absolute rate below is a basis – except for the spray dryer, whose hardware this flowsheet models, so its rate IS the dryer's capacity.

TWO RECYCLES, both declared in system/solverDict: the drying gas (gasRecycle) and the compactor fines (finesRecycle). The recovered acetone is NOT recycled in this base case: it goes to a tank, for QC and reuse – the README says why, and closing that loop is a group's question.

WHAT IS A PLACEHOLDER. The blenders, the roller compactor, the mill, the screen, the tablet press and the packaging line are FLOW PRIMITIVES (a 'mixer', a 'splitter'): they conserve mass and energy and model NOTHING of the machine – no blend uniformity, no ribbon density, no particle-size reduction, no compaction force, no tablet hardness. Choupo has no such equipment model; none is invented here.

The coating pan is TWO boxes, a ‘mixer‘ (the spray lands on the cores) and a ‘solidDryer‘ (the hot air takes the water off), which is the mass and energy balance of one machine.

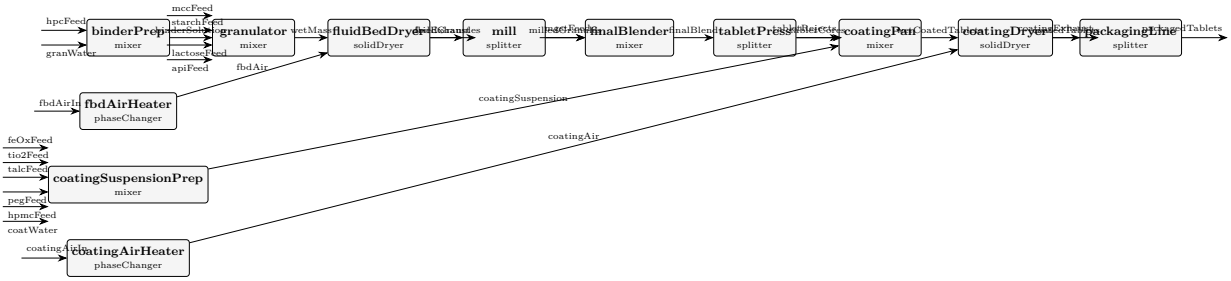
A BASE CASE for a pharmaceutical-industry project group (DEV.md 4c C97, phase A; re-based on a sourced design basis in C110). The plant makes film-coated tablets of apalutamide: the active pharmaceutical ingredient (API) is bought, everything else is made on site — the spray-dried solid dispersion, the granules, the tablets, the coat and the packs. It runs (a few seconds from a cold start), it converges, its mass and energy balances close, and it is deliberately NOT optimised — every number a group would change is a plain key, and every one says where it came from.

The case is sealed: everything it reads is in its own constant/.

Its design basis is a dossier, not a guess: [docs/design/apalutamide-design-basis-dossier.md](https://github.com/choupo-admin/choupo/blob/main/docs/design/apalutamide-design-basis-dossier.md) ("the dossier" below) — the EMA and FDA assessment reports, the label, the originator's patent, the originator's published sales, generic-price evidence and a red-team review, every number with its source, page and a confidence word (∗stated∗, ∗derived∗, ∗estimate∗, ∗not found∗). Read it before you change anything: most of what you will be asked to defend is already argued there, and what is NOT is listed in its section 6 as the questions only a supplier or the originator can answer.

Read section 3 before anything else. Half of this plant is physics Choupo computes (the spray dryer, the nitrogen loop, the solvent recovery, the coating dryer, the heat exchangers); the other half is a mass balance with no equipment model at all (blending, compaction, milling, screening, tableting, packaging). The two halves look alike in the stream table. They are not alike.

The amorphous dispersion this plant makes — apalutamide in HPMCAS, 1:3, spray dried — is claimed by an active patent family of the originator (US 12,303,493 B2, Aragon Pharmaceuticals / Janssen: claim 1 the dispersion, claim 4 the 1:3 ratio, claim 10 spray drying, claims 18 and 20 the 60 mg and 240 mg tablets; anticipated expiry 3 Dec 2035, an assumption by Google Patents, not a legal conclusion; the European counterparts and their SPCs were NOT verified — dossier section 3.6). A plant that copies this formulation and sells before then infringes, unless the patents fall.



So the case declares its business case, as Vitor ruled (DEV.md 4c C99 addendum): a generic entrant to the European market at loss of exclusivity. Three consequences, each in the case:

donepezil01_tablets

tutorials/batch/plant/donepezil01_tablets

What it does: DONEPEZIL HYDROCHLORIDE 10 mg FILM-COATED TABLETS, a drug-product plant (the API is BOUGHT): WET GRANULATION – the API, lactose monohydrate, maize starch and microcrystalline cellulose wetted in a high-shear granulator with an aqueous hydroxypropyl-cellulose binder solution and dried in a fluid bed ('solidDryer', hot air, the starch's sorption isotherm) – milling, a final blend with magnesium stearate, tableting with rejects, an aqueous hypromellose film coat dried off by hot air, and packaging. The excipients are the reference product's (ARICEPT SmPC section 6.1) and the 174.33 mg of lactose per 10 mg tablet is its section 2; every other quantity is an author-set assumption. The steady flowsheet is the material balance per unit of product (720 000 tablets/h pressed, the fluid bed's own drying rate, is a basis); a BATCH PLAN (system/postDict) sizes each step for a 300 kg lot, counts the lots a year for 150 million tablets, and finds the pace of the granulation and tableting trains. Blending, granulation, milling, tableting and packaging are MASS-BALANCE PLACEHOLDERS (no equipment physics). No organic solvent, no spray drying, no hazardous area. One strength (10 mg); the two-strength year on the same equipment, campaigns and changeovers, is donepezil02_two_strengths.

The story: a drug-product plant: donepezil hydrochloride 10 mg film-coated tablets. The API is BOUGHT; everything else is made here (DEV.md 4c C104, built on the stated defaults of C110). A BASE CASE: it runs, it is NOT optimised, and every number a group would change is a plain key, said to be an assumption where it is declared. The README is the narrative; this file is the topology.

THE BASIS (README section 2): 720 000 tablets per hour PRESSED, the flowsheet basis, of a 280 mg core carrying 10 mg of donepezil hydrochloride and 174.33 mg of lactose monohydrate (the reference product's own figures), with a 3 % film coat. THIS STEADY FLOWSHEET IS THE MATERIAL BALANCE PER UNIT OF PRODUCT (DEV.md 4c C99): the plant runs in BATCHES (lots released one by one), and the BATCH PLAN in system/postDict sizes each step for one lot from these streams' masses, counts the lots a year from the declared production, and finds the step that paces each train. The absolute rate is chosen as the fluid bed's own DRYING rate (one 300 kg lot dried in 1.5 h), so the fluid bed's air heater is sized for the duty it really has; the coater's heater is then sized at that same rate, which is about twice the coater's own – README section 6.

WET GRANULATION granWater + hpcFeed → [binderPrep] → binderSolution –+ apiFeed (BOUGHT) + lactose + starch + MCC ————+→ [granulator] → wetMass fbdAirIn → [fbdAirHeater] 333 K → fbdAir | wetMass + fbdAir → [fluidBedDryer] → driedGranules + fbdExhaust driedGranules → [mill] → milledGranules

NO RECYCLE, NO SOLVENT. Unlike apalutamide01_tablets there is no spray dryer, no organic solvent, no nitrogen loop, no solvent recovery and no hazardous area: an aqueous wet granulation and an aqueous coat.

WHAT IS A PLACEHOLDER. The high-shear granulator, the mill, the final blender, the tablet press and the packaging line are FLOW PRIMITIVES (a 'mixer', a 'splitter'): they conserve mass and energy and model NOTHING of the machine – no granule growth, no granule size, no blend uniformity (THE critical quality question of a low-dose tablet, README section 8), no compaction force, no tablet hardness. Choupo has no such equipment model; none is invented here. The two DRYERS are physics: 'solidDryer' dries to the starch's sorption isotherm at the INLET air's humidity (a batch dried to its end point ends in

equilibrium with the fresh air), with the energy balance on the package's enthalpy. The coating pan is TWO boxes, a 'mixer' (the spray lands on the cores) and a 'solidDryer' (the hot air takes the water off), which is the mass and energy balance of one machine.

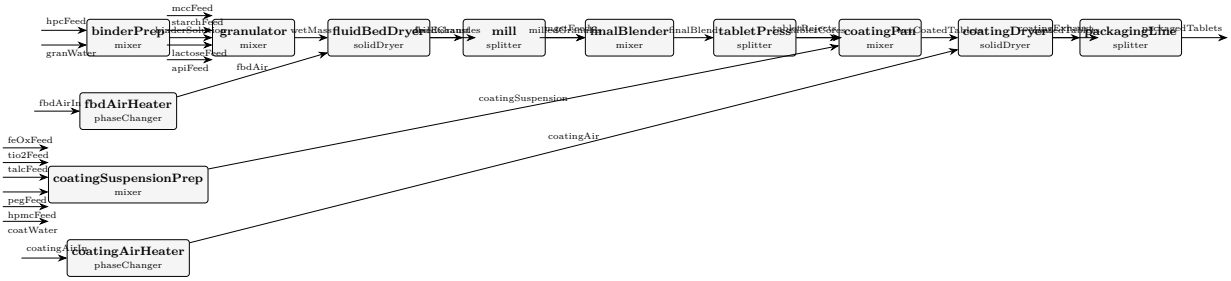
A BASE CASE for a pharmaceutical-industry project group (DEV.md 4c C104, built on the stated defaults of C110). The plant makes film-coated tablets of donepezil hydrochloride by wet granulation: the active pharmaceutical ingredient (API) is bought, everything else is made on site — the granules, the tablets, the coat and the packs. It runs (in seconds), its mass and energy balances close, and it is deliberately NOT optimised — every number a group would change is a plain key, said to be an assumption where it is declared.

The case is sealed: everything it reads is in its own constant/.

It is the simpler sibling of apalutamide01_tablets (the same folder, the same grammar, read that case's README for anything not repeated here). There is no spray drying, no organic solvent, no nitrogen loop, no solvent recovery and no hazardous area (ATEX): an aqueous binder, an aqueous coat, two hot-air dryers. What is harder here is not the chemistry but the dose: 10 mg of API in a 280 mg core (section 8).

Read section 3 before anything else. Two units of this plant are physics Choupo computes (the fluid-bed dryer and the coating dryer, with their air heaters); the rest is a mass balance with no equipment model at all (granulation, milling, blending, tableting, packaging). The two look alike in the stream table. They are not alike.

Two inferences, labelled as such: the lactose of the two strengths is in the ratio 2:1, which is what ONE common blend pressed at two tablet weights would give (a dose-proportional pair); and the yellow iron oxide is the only ingredient the two strengths do not share — so the two products can share the whole granulation and differ only from the press on.



Where the group must look for what this case could not verify: ARICEPT was not authorised through the EMA's centralised procedure as far as this case could find, so there is no EPAR to read; the national SmPCs and public assessment reports (MHRA, HPRA, the other national agencies) and the public assessment reports of the generic donepezil products (written for each generic's authorisation, and which may describe its manufacturing route) are where the formulation and the process are described; the Ph. Eur. monographs of the excipients for their grades. Replace each assumption with what you find, and cite it.

donepezil02_two_strengths

tutorials/batch/plant/donepezil02_two_strengths

What it does: DONEPEZIL HYDROCHLORIDE 10 mg AND 5 mg FILM-COATED TABLETS, TWO PRODUCTS in campaigns on one drug-product plant (the API is BOUGHT): WET GRANULATION – the API, lactose monohydrate, maize starch and microcrystalline cellulose wetted in a high-shear granulator with an aqueous hydroxypropyl-cellulose binder solution and dried in a fluid bed ('solidDryer', hot air, the starch's sorption isotherm) – milling, a final blend with magnesium stearate, tableting with rejects, an aqueous hypromellose film coat dried off by hot air, and packaging. The excipients are the reference product's (ARICEPT SmPC section 6.1) and the 174.33 mg of lactose per 10 mg tablet is its section 2; every other quantity is an author-set assumption. The steady flowsheet is the material balance per unit of product (720 000 tablets/h pressed, the fluid bed's own drying rate, is a basis); a MULTIPRODUCT BATCH PLAN (system/postDict) sizes each step for a 300 kg lot of either strength, counts the lots a year for 90 million 10 mg and 60 million 5 mg tablets, runs them in single-product campaigns in a declared order with a direction-dependent clean between them (colour carry-over: white after yellow is the long one), and finds the pace of the granulation and tableting trains. Blending, granulation, milling, tableting and packaging are MASS-BALANCE PLACEHOLDERS (no equipment physics). No organic solvent, no spray drying, no hazardous area. The 5 mg tablet is the 10 mg tablet at half the weight (the same blend), so the one steady balance serves both.

The story: a drug-product plant: donepezil hydrochloride 10 mg AND 5 mg film-coated tablets, two products in campaigns on one plant (the steady balance below is both strengths': the 5 mg tablet is the 10 mg tablet at half the weight, README section 2). The API is BOUGHT; everything else is made here (DEV.md 4c C104, built on the stated defaults of C110). A BASE CASE: it runs, it is NOT optimised, and every number a group would change is a plain key, said to be an assumption where it is declared. The README is the narrative; this file is the topology.

THE BASIS (README section 2): 720 000 tablets per hour PRESSED, the flowsheet basis, of a 280 mg core carrying 10 mg of donepezil hydrochloride and 174.33 mg of lactose monohydrate (the reference product's own figures), with a 3 % film coat. THIS STEADY FLOWSHEET IS THE MATERIAL BALANCE PER UNIT OF PRODUCT (DEV.md 4c C99): the plant runs in BATCHES (lots released one by one), and the BATCH PLAN in system/postDict sizes each step for one lot from these streams' masses, counts the lots a year from the declared production, and finds the step that paces each train. The absolute rate is chosen as the fluid bed's own DRYING rate (one 300 kg lot dried in 1.5 h), so the fluid bed's air heater is sized for the duty it really has; the coater's heater is then sized at that same rate, which is about twice the coater's own – README section 6.

WET GRANULATION granWater + hpcFeed → [binderPrep] → binderSolution –+ apiFeed (BOUGHT) + lactose + starch + MCC ————+→ [granulator] → wetMass fbdAirIn → [fbdAirHeater] 333 K → fbdAir | wetMass + fbdAir → [fluidBedDryer] → driedGranules + fbdExhaust driedGranules → [mill] → milledGranules

FINAL BLEND, TABLETING, COATING, PACKAGING milledGranules + mgstFeed → [finalBlender] → finalBlend → [tabletPress] → tabletCores +→ tabletRejects coatWater + HPMC + macrogol + talc + TiO2 + yellow iron oxide → [coatingSuspensionPrep] tabletCores + coatingSuspension → [coatingPan] → wetCoatedTablets coatingAirIn → [coatingAirHeater] 333 K → coatingAir wetCoatedTablets + coatingAir → [coatingDryer] → coatedTablets + coatingExhaust coatedTablets → [packagingLine] → packagedTablets

NO RECYCLE, NO SOLVENT. Unlike apalutamide01_tablets there is no spray dryer, no organic solvent, no nitrogen loop, no solvent recovery and no hazardous area: an aqueous wet granulation and an aqueous coat.

WHAT IS A PLACEHOLDER. The high-shear granulator, the mill, the final blender, the tablet press and the packaging line are FLOW PRIMITIVES (a 'mixer', a 'splitter'): they conserve mass and energy and model NOTHING of the machine – no granule growth, no granule size, no blend uniformity (THE critical quality question of a low-dose tablet, README section 8), no compaction force, no tablet hardness. Choupo has no such equipment model; none is invented here. The two DRYERS are physics: 'solidDryer' dries to the starch's sorption isotherm at the INLET air's humidity (a batch dried to its end point ends in equilibrium with the fresh air), with the energy balance on the package's enthalpy. The coating pan is TWO boxes, a 'mixer' (the spray lands on the cores) and a 'solidDryer' (the hot air takes the water off), which is the mass and energy balance of one machine.

1. Explain the base result. The plant makes 150 million tablets (34 828 kg) in 115 lots and loses money: NPV -28.96 M EUR. Find the term of COM_d that makes the loss (compare 2.73 C_OL with 1.23 (C_RM + C_UT) in the Economic Appraisal), and use the Bases table of the batch plan so that 300 kg, 305.9 kg, 168 h, 880 h, 2079 h and 3840 h each mean one thing. 2. Find the constraint that matters. Two different words: the limiting stage (sets T_L) of each train — drying (4.25 h a lot) on granulation, packaging (11 h a 10 mg lot, 20 h a 5 mg lot) on tableting — and the machine with the least capacity margin, the granulator at 92.8 % of its bowl. Say which one limits the lot and which one the year. 3. Propose one improvement and justify it with a new run. Change ONE declaration (the crew, the lot, outOfPhase 2 on packaging, the campaign length), run again, and show the number that moved and the one that did not.

A BASE CASE for a pharmaceutical-industry project group (DEV.md 4c C249). It takes the plant of donepezil01_tablets (wet granulation, an aqueous coat, the API bought) and asks the question that case could not answer: how is a year divided between two strengths made on the same equipment, and what does it cost to change from one to the other? The answer is a multiproduct batch plan — single-product campaigns in a declared order, a clean between products that depends on the direction of the change, and a Gantt chart of the year. It runs (in seconds), it is deliberately NOT optimised, and every number a group would change is a plain key, said to be an assumption where it is declared.

The case is sealed: everything it reads is in its own constant/. The flowsheet, the components and the building are donepezil01_tablets' own, unchanged (read that README for the chemistry, the dryers and the questions about content uniformity); this one is about the plan.

One steady flowsheet serves both, because the 5 mg tablet is the same blend at half the weight: a kilogram of either carries the same kilograms of every ingredient, and the batch plan reads its balance per kg of product (BatchPlanPass.H:189-193). The one thing that would differ — the 10 mg coat's 1 % yellow iron oxide, 0.03 % of the tablet — is ignored here and said so; a group that wants it declares a massPerProduct for the coating suspension and the plan announces ownBalance.

Two trains decoupled by the final-blend store, as in donepezil01_tablets; lotsPerCampaign 8 and a 24 h full clean between campaigns of ONE product. Between the two products every stage has its own clean (productChangeover) and the train waits for the slowest. The Gantt of the year (campaignOrder (strength10 strength5)):

The tableting train is paced by the packaging line for both products, but at 11 h a lot for one and 20 h for the other: the limiting stage is a property of the product, not only of the plant. Equipment is sized for the product that needs the most (the plan names it, sizing by): here the 10 mg for every stage, because the 5 mg lot is the same mass and only takes longer.

reactor

The theory you need. Three idealised steady reactors. Conversion reactor: stoichiometry only, $n_{\text{out}} = n_{\text{in}} + \nu\,\xi$, duty from the ONE enthalpy base $\Delta H_{\text{rxn}}(T) = \sum_i \nu_i h_i(T)$ (formation datum – no separate "heat of reaction" input, and any dict override is cross-checked aloud). CSTR: outlet at reactor conditions with rate $r(c_{\text{out}}, T)$, so $F\,(c_{\text{in}} - c_{\text{out}}) = r\,V$. PFR: the same rate integrated along the volume, $\mathrm{d}F_i/\mathrm{d}V = \nu_i\,r$. Arrhenius kinetics $k = A\,T^b e^{-E_a/RT}$, orders from the dict, reverse rates from the equilibrium constant (thermo-consistent by construction). Expect: CSTR conversion below PFR at equal volume (back-mixing), exponential T sensitivity, and equilibrium limits the kinetics can approach but never cross. *Full derivation: Theory Guide, the reaction-engineering chapter.*

batch01_first_order

tutorials/batch/reactor/batch01_first_order

What it does: Isothermal batch Fischer esterification (AcOH + EtOH <→ EtOAc + H2O) at 350 K, pseudo-first-order in ethanol; analytical exp-decay comparison

The story: isothermal pseudo-first-order batch reactor.

Single vessel, pseudo-first-order esterification (AcOH + EtOH → EtOAc + H2O, rate = k.[ethanol]). Initial charge is an equimolar ethanol + acetic acid mix; kinetics from the reactions library (Arrhenius A=1e8 1/s, Ea=70 kJ/mol). At T = 350 K:

k(T) = 1e8 · exp(-70000 / (8.314 · 350)) ≈ 3.57e-3 s^-1 τ = 1/k ≈ 280 s

Analytical solution for first-order in a constant-volume batch:

n_A(t) = n_A(0) · exp(-k t)

The simulator integrates dn_A/dt = -k · (n_A / V) · V = -k n_A with RK4 at dt = 1 s; final t = 600 s gives X_A ≈ 1 - exp(-k·600) ≈ 1 - exp(-2.14) ≈ 0.882

18.5 mol of an equimolar ethanol / acetic-acid charge (about a litre) is held at 350 K in a closed vessel for 600 s and the Fischer esterification runs — the kinetics of cstr01, now integrated in time by RK4 at 1 s steps. The golden: ethanol falls from 9.25 mol to 1.083 mol (X = 88.3 %), 8.167 mol of ethyl acetate made, and the jacket has removed only 17.18 kJ to hold the temperature — exactly -2.10 kJ/mol of reaction at 350 K, the elements-datum heat every reactor in Choupo prices on. The liquid esterification is only mildly exothermic (calorimetry: about -3 to -4 kJ/mol), so the jacket duty here is small, not the cooling load an exotherm of tens of kJ/mol would need.

1. choupoBatch, not choupoSolve. A batch vessel has no steady state; the case declares endTime 600; deltaT 1.0; writeInterval 30; in controlDict and the engine integrates dn/dt = ν r V. The Log tab prints a snapshot every 30 s: four inventories and T. 2. First order means an exponential, and you can check it. With k = 3.575e-3 s?[1] at 350 K (the same Arrhenius pair as cstr01), n(600 s) = 9.25·e^(-2.145) = 1.083 mol. The table is that curve, sampled. 3. The campaign ledger closes at machine precision. [campaign] mass balance ? closure 4.5e-16, energy balance: dH_vessels = -17.18 kJ ? = Q_ledger -17.18 kJ, closure 0 — every joule the jacket took is a state difference on the charge, never a quadrature, which is why the closure is zero and not merely small. 4. A CSTR at the same τ does worse. 600 s here gives 88 %; the continuous reactor at τ = 310 s gave 53 % and a PFR 67 %. Three reactors, one rate law, three answers — the batch one is the upper envelope, because nothing leaves early.

Set T_setpoint 370 K;: k roughly triples, the exponential steepens, and the ledger's Q follows the extent (small, because the reaction is only mildly exothermic). Then batch02_adiabatic removes the jacket, and T becomes one more state on the trajectory.

batch01b_first_order_eulersi

tutorials/batch/reactor/batch01b_first_order_eulersi

What it does: GREEN WITNESS: semi-implicit Euler (EulerSI) on batch01 mild isothermal esterification – first order suffices off-stiffness; twin of the ignition01_h2o2_eulersi expected failure.

The story: GREEN WITNESS for the EulerSI integrator: batch01's mild isothermal esterification, integrated by semi-implicit (linearly-implicit) Euler instead of the RK4 default. On a non-stiff problem the first-order method simply works, and the golden pins that its answer agrees with the physics batch01 already pins. Its EXPECTED-FAILURE twin is ignition01_h2o2_eulersi (stiff nonlinear ignition, where first order goes unphysical and the engine refuses by name). Registered model no case selected until 2026-08-22 (invariant I8).

batch02_adiabatic

tutorials/batch/reactor/batch02_adiabatic

What it does: Adiabatic batch esterification (AcOH + EtOH → EtOAc + H2O), starting cold (320 K); the nearly thermoneutral liquid reaction warms the batch only ~2 K in 600 s and is ~22 % complete (thermal runaway needs an exothermic reaction; replacement case planned)

The story: pseudo-first-order esterification (AcOH + EtOH → EtOAc + H2O) in an adiabatic batch reactor, starting cold.

T_0 = 320 K (k_0 ~ 3.7e-4 s^-1, tau_0 ~ 2700 s). dH_rxn = -2.43 kJ/mol of ethanol at 320 K, computed from the species' standardThermochemistry (elements datum; the engine's own '[reaction heat]' line). It is about ten times smaller than the -26.06 kJ/mol this case used to print: the acetic-acid correction (docs/design/acetic-acid-latent-heat-closure.md) made the liquid esterification nearly thermoneutral. Equimolar ethanol + acetic acid charge; ethyl acetate + water are the products. Mass-conserving, so the energy balance is clean. Result: T rises only 320 → 322.2 K in the 600 s window, and the reaction is only ~22 % complete at the end (it used to reach 428 K and complete conversion). There is no runaway and no plateau; the rate barely accelerates because T barely moves. The adiabatic ODE conserves a frozen-dH surrogate (dH_rxn pinned at the charge T), which the run announces.

The original teaching point of this case (thermal runaway: induction, then a sharp temperature rise, then a plateau) needs a genuinely exothermic reaction; a replacement case on such a reaction is planned. No parameter was changed to recover the runaway.

The energy balance is just:

dT/dt = - r * V * dH_rxn / (n_A * Cp_A + n_B * Cp_B)

Constant-Cp here (polynomial degree 0 for both ethanol and water in the database), so the result extrapolates linearly above the nominal liquidHeatCapacity Trange (280-373 K) without numerical pathology.

What to expect (golden-locked):

kind	unit/stream	key	expected

batch03_consecutive

tutorials/batch/reactor/batch03_consecutive

What it does: Isothermal batch reactor: consecutive A → B → C with k1 > k2; intermediate B peaks then decays

The story: two first-order reactions in series:

with k1 > k2. This is the textbook series-reaction setup: B is produced from A faster than it is consumed to C, so n_B grows at first, reaches a maximum, then decays as A runs out.

Analytical solution (constant V, isothermal, first-order):

n_A(t) = n_A0 ∗ exp(-k1 t) n_B(t) = n_A0 ∗ k1 / (k2 - k1) ∗ [exp(-k1 t) - exp(-k2 t)] n_C(t) = n_A0 - n_A(t) - n_B(t)

t_max = ln(k1 / k2) / (k1 - k2)

With k1 = 0.01 1/s and k2 = 0.002 1/s:

t_max = ln(5) / 0.008 ~ 201 s n_B_max / n_A0 = (k1/k2)^(k2/(k2-k1)) = 5^(-0.25) ~ 0.669

The case demonstrates: 1. multi-reaction support in BatchReactor (v0.21); 2. time-dependent selectivity — harvesting B at t ~ 200 s maximises yield, waiting longer wastes B to C.

No species supplies activation energy: both A_pre are quoted with Ea = 0 so that the rate constants are exactly the values above regardless of T (the case is isothermal anyway).

batch04_reversible_wgs

tutorials/batch/reactor/batch04_reversible_wgs

What it does: Batch reversible water-gas shift (CO + H2O <→ CO2 + H2) at 600 K; conversion relaxes to X_eq

The story: the reversible water-gas shift in a closed BATCH reactor (choupoBatch), the time-domain sibling of cstr02 / pfr02.

Equimolar CO + H2O charged at 600 K. The forward Arrhenius rate drives conversion up; the reverse term (k_rev = k_fwd / K_eq, K_eq from the four species' g_pure_ig, re-evaluated each step) brakes it. The batch trajectory relaxes onto the SAME thermodynamic ceiling the CSTR and PFR reached — X → X_eq ~ 0.84 — then sits there (net rate → 0), instead of running to X = 1.

The forward A is the illustrative value tuned for stable RK4 (see constant/reactions); the equilibrium X_eq is A-independent.

batch04_transient_dirs

tutorials/batch/reactor/batch04_transient_dirs

What it does: Adiabatic batch esterification with OpenFOAM-style REAL-TIME instant dirs: scrub 0/ 30/ 60/ ... s to watch conversion climb to ~0.22 while T rises only 320 → 322 K (the runaway of the old exotherm is gone; replacement case planned)

The story: the batch02_adiabatic case re-run with REAL-TIME instant directories: the integrator dumps 0/ 30/ 60/ ... s snapshots (OpenFOAM-style) so the trajectory – conversion 0 → ~0.22, T 320 → 322.2 K – can be scrubbed frame by frame in the GUI.

The physics below is inherited from batch02_adiabatic, unchanged: pseudo-first-order esterification (AcOH + EtOH → EtOAc + H2O) in an adiabatic batch reactor.

T_0 = 320 K (k_0 ~ 3.7e-4 s^-1, tau_0 ~ 2700 s). dH_rxn = -2.43 kJ/mol of ethanol at 320 K, computed from the species' standardThermochemistry (elements datum; the engine's own '[reaction heat]' line). It is about ten times smaller than the -26.06 kJ/mol this case used to print: the acetic-acid correction (docs/design/acetic-acid-latent-heat-closure.md) made the liquid esterification nearly thermoneutral. Equimolar ethanol + acetic acid charge; ethyl acetate + water are the products. Mass-conserving, so the energy balance is clean. Result: T rises only 320 → 322.2 K in the 600 s window, and the reaction is only ~22 % complete at the end (it used to reach 428 K and complete conversion). There is no runaway and no plateau; the rate barely accelerates because T barely moves. The adiabatic ODE conserves a frozen-dH surrogate (dH_rxn pinned at the charge T), which the run announces.

The original teaching point of this case (thermal runaway: induction, then a sharp temperature rise, then a plateau) needs a genuinely exothermic reaction; a replacement case on such a reaction is planned. No parameter was changed to recover the runaway.

The energy balance is just:

batch06_adaptive_runaway

tutorials/batch/reactor/batch06_adaptive_runaway

What it does: Adiabatic esterification (AcOH+EtOH), nearly thermoneutral after the acetic-acid correction; ADAPTIVE Rosenbrock23 time-stepping — the step grows as the transient settles (glass-box step history; the thermal runaway of the old exotherm is gone, replacement case planned)

The story: the batch02_adiabatic esterification integrated with ADAPTIVE Rosenbrock23 time-stepping, the step history printed glass-box so the student sees the controller at work. (The directory name keeps "runaway" from the old exotherm; there is no runaway any more.)

The physics below is inherited from batch02_adiabatic, unchanged: pseudo-first-order esterification (AcOH + EtOH → EtOAc + H2O) in an adiabatic batch reactor.

T_0 = 320 K (k_0 ~ 3.7e-4 s^-1, tau_0 ~ 2700 s). dH_rxn = -2.43 kJ/mol of ethanol at 320 K, computed from the species' standardThermochemistry (elements datum; the engine's own '[reaction heat]' line). It is about ten times smaller than the -26.06 kJ/mol this case used to print: the acetic-acid correction (docs/design/acetic-acid-latent-heat-closure.md) made the liquid esterification nearly thermoneutral. batch07_lhhw_methylAcetate

tutorials/batch/reactor/batch07_lhhw_methylAcetate

What it does: LHHW in a BATCH reactor: methyl-acetate synthesis over Amberlyst 15 (Popken 2000, Eq 16)

The story: the SAME rate law as cstr07, in a BATCH vessel.

CH3OH + CH3COOH <→ CH3COOCH3 + H2O over Amberlyst 15

Popken, Gotze & Gmehling, Ind. Eng. Chem. Res. 39 (2000) 2601, Eq 16: the adsorption-based LHHW on UNIQUAC activities. Nothing about the rate law is restated here – it lives in constant/reactions, exactly as the steady CSTR reads it, because the SAME 'RateLaw' evaluates it in both. A batch reactor and a continuous one cannot disagree about what an adsorption denominator means.

What changes is only what a batch vessel does with a rate: it integrates it. The charge is equimolar methanol + acetic acid; the trajectory climbs to the ACTIVITY equilibrium, X = 76.6 %, and stops. That plateau is asserted nowhere: it is where k1 a'_HOAc a'_MeOH = k-1 a'_MeOAc a'_H2O, i.e. the K_a = 25.50 the authors' independent Eq 17 recovers from the same eight constants – and the same number the steady CSTR climbs to as its volume grows. Two reactors, two integration schemes, one equilibrium.

Water is the strongest adsorber (K/M = 0.29 against 0.052 for the acid), so as the reaction MAKES water it crowds the acid off the resin and the denominator grows. That self-inhibition is why reactive distillation, which pulls the water out as it forms, is worth its capital.

Do NOT try to see the inhibition by deleting the 'adsorption' block and keeping k1. It tells you nothing: the constants were REGRESSED for this rate law, on these activities, and a rate constant without its rate law is a number without a meaning. (Delete the denominator and the reaction gets FASTER, because the adsorbed activities a' are small and dividing by their square is a multiplication. That is an arithmetic accident, not physics.) To SEE the inhibition, spike the charge with water at the same acid and alcohol fractions:

methanol 0.4, aceticAcid 0.4, water 0.0 → initial rate 58.3 mmol/(L.s) methanol 0.4, aceticAcid 0.4, water 0.2 → initial rate 29.0 mmol/(L.s)

Half the rate, with every reactant fraction unchanged. The water is not a reactant here; it is sitting on the sites.

'catalystLoading' (kg of dry resin per m^3) is what turns the paper's per-gram rate constants into a volumetric rate. With concentrations in kmol/m^3 the conversion is exact and unit-free: mol/(g.s) x kg/m^3 = kmol/(m^3.s).

The vessel runs isothermal at 333.15 K, the top of the authors' data range. Do not extrapolate: their activation energies are APPARENT values, fitted over 303-333 K.

batch26_cooling_failure

tutorials/batch/reactor/batch26_cooling_failure

What it does: Cooling failure on a batch (fictitious A + B → P in solvent S): isothermal at 330 K, the jacket stops at t_f, the accumulated B drives T to T_cf

The story: a BATCH exothermic reaction held at T_p by its jacket, and what happens when the jacket stops.

THE REACTION IS FICTITIOUS: A + B → P in an inert solvent S, an ideal liquid with no vapour phase in the reactor (constant/reactions and constant/components/reactantA.dat say how every number was set). It is a teaching witness for the process-safety EduTool, not a model of any real chemistry, and its records are coherent by construction: the heat of reaction, -60.000 kJ per mol of B, comes from formation data whose differences are the only thing that carries meaning, and it does not depend on temperature (dCp = 0). The whole charge – 5 mol A, 5 mol B, 15 mol S – is in the vessel at t = 0. That is what makes a batch the WORST case for thermal safety: at t = 0 all of the reactant is unconverted, so a cooling failure at the start releases the whole adiabatic temperature rise.

THE SCENARIO (the recipe below):

t < t_f isothermal at T_p = 330 K; the jacket removes the heat of reaction (the energy ledger records that duty) t = t_f 'setParameter reactor adiabatic 1' – the jacket stops t > t_f adiabatic: the B still unconverted at t_f (the ACCUMULATION, X_ac) reacts and heats the mass to T_cf

The thermal-safety estimate is T_cf = T_p + X_ac ∗ dT_ad (a batch's mass does not change, so Stoessel's semi-batch mass correction is 1), with dT_ad the adiabatic rise of the full charge from T_p (run this case with the failure at t = 0 to have the engine compute it). Because dCp = 0 here, the total heat capacity of the charge does not change as it reacts, and the estimate is EXACT for this batch: the engine's T_cf (T_final of a failure run) and the estimate agree to the integration error. The MTSR is the largest T_cf over every failure instant: for a batch, the failure at t = 0.

'value 0' on the same event keeps the jacket working: the same case then runs the normal isothermal batch, which is how the EduTool draws X_ac(t).

WHAT IS NOT MODELLED: the vessel has no vapour phase – past the mixture's boiling point a real open vessel would boil and a closed one would pressurise. The MTSR is defined on exactly that hypothetical, which is why it is compared with the boiling point (MTT) rather than trusted beyond it. No decomposition is modelled either: T_D24 is an assumption the EduTool's reader sets.

batch27_semibatch_dosing

tutorials/batch/reactor/batch27_semibatch_dosing

What it does: Semi-batch (fictitious A + B → P in solvent S): B dosed in 16 portions over 4 h at 330 K, the jacket fails after the last portion, the small accumulation keeps T_cf low

The story: the SAME fictitious reaction as batch26 (A + B → P in the inert solvent S), the same totals, the same T_p, run SEMI-BATCH: A and the solvent are in the reactor and B is DOSED, a sixteenth at a time every 15 minutes, over four hours. Then the jacket fails.

This is the inherently safer answer to batch26 in Kletz's sense of limiting what is there: a batch reactor holds all of its reactant at t = 0; a dosed reactor holds only what it has been given and has not yet converted. That unconverted inventory – the ACCUMULATION – is what a cooling failure turns into temperature, so limiting it limits the maximum temperature of the synthesis reaction (MTSR). The lever is the DOSING RATE against the REACTION RATE: dose faster than the reaction consumes and the reactor fills with unreacted B, which is a batch again.

THE DOSING is written as portions, each a recipe 'transfer' from the dosing tank, because a recipe transfer is what choupoBatch has: a batchReactor carries no continuous feed. Portion-wise addition is also how a hazardous reagent is often added in practice. Each transfer moves a FRACTION of what is left in the tank (1/16, then 1/15, ... then 1), so every portion is 1/16 of B. The dosing tank is at T_p, so the feed brings no sensible-heat effect into the isothermal reactor (into a hot adiabatic one the dose is mixed by enthalpy equality and cools it a little; a cold feed would take more of the reaction's heat – left out on purpose). With discrete doses the accumulation jumps at each portion, so the worst instant for a failure is RIGHT AFTER a portion; the trajectory row at a portion's instant is written after the transfer.

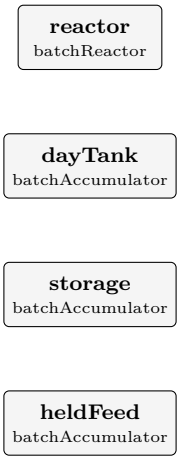
THE TWO SAFETY EVENTS come first in the recipe:

1. the COOLING FAILURE at t_f ('adiabatic 1'; '0' keeps the jacket); 2. what happens to the FEED at the same instant, one transfer with three readings: 'to heldFeed; fraction 1;' the DOSING INTERLOCK works: the methodology's assumption that the feed stops when the cooling does. A recipe transfer has no valve, so the interlock is written as what it achieves – everything left in the dosing tank is moved to 'heldFeed', a vessel nothing is ever dosed from, and every later portion moves a fraction of an empty tank, which is nothing. 'fraction 0;' the interlock FAILS: nothing is held back and the pump keeps dosing into an adiabatic reactor, at its rate. 'to reactor; fraction 1;' the WHOLE dosing tank enters the reactor at once (a valve left open, a pump run away): the worst a feed failure can do, bounded only by what the tank holds. A flow-limited pump limits the RATE, not the TOTAL: with the whole of B in the tank, that total is the batch's. In a plant an interlock is a sensor, a logic solver and a valve, each of which can fail; here it is one line, and the EduTool runs it all three ways. batch28_dosing_vessel_limit is the same reactor with a dosing vessel that holds only a quarter of B.

Normal operation, for the accumulation curve: the failure at 'value 0' and the feed event at 'fraction 0'.

The shipped t_f is 1 s after the last portion, where the accumulation is close to its largest – NOT where the temperature after a failure is largest: early in the dosing the accumulation heats a smaller mass (Stoessel's M_f/M(t) correction), so the MTSR comes earlier; the EduTool shows where, and confirms it with the engine at every post-portion instant.

WHAT IS NOT MODELLED, besides what batch26 names: the reactor's volume is held at its declared value while the dosing adds liquid (a batchReactor does not grow its volume on a charge). The rate law is



first order in B and zero order in A, so the extent rate k n_B does not depend on V and this changes no number here; a rate law with a concentration term of another order would be wrong.

batch28_dosing_vessel_limit

tutorials/batch/reactor/batch28_dosing_vessel_limit

What it does: Semi-batch with a day tank that holds a quarter of B (fictitious A + B → P in solvent S): the cooling fails and the whole day tank enters the reactor at once; T_cf stays low

The story: batch27 with the DOSING VESSEL SIZED so that a feed failure cannot take the reactor past its limits.

The same fictitious reaction (A + B → P in the inert solvent S), the same totals, the same T_p and the same sixteen portions, one every 15 minutes. What changes is where B waits. In batch27 the dosing tank holds ALL of B, so the worst a feed failure can do – the whole tank entering at once, or the pump running on with no interlock to stop it – delivers the batch's charge: a flow-limited pump limits the RATE, not the TOTAL. Here the only vessel connected to the reactor is a DAY TANK that holds a QUARTER of B (four portions). It is refilled from storage three times, each refill made only once the day tank is empty, between two portions; storage has no line to the reactor.

THE FAILURE SCENARIO (the first three recipe events, all at t_f):

1. the COOLING FAILURE ('adiabatic 1'; '0' keeps the jacket); 2. the WORST FEED FAILURE: the WHOLE day tank enters the reactor at once ('to reactor; fraction 1;'). 'to heldFeed; fraction 1;' is the interlock holding it back, 'fraction 0;' the pump running on through its remaining portions – which delivers the same total, only later; 3. NO REFILL after a failure: what is left in storage is moved to 'heldFeed' ('fraction 1'; 'fraction 0' in normal operation).

Event 3 is the honest limit of the claim. The day tank's size removes the dependence on the DOSING interlock; what remains is the refill, which is a discrete, deliberate act taken when the day tank is empty and the reactor's state is known – a procedure, or an interlock of its own. The page says so; it does not hide it inside the word "inherent".

With the whole day tank entering, the worst instant is right after a refill (or at t = 0), when the tank is full: the B that can reach the reactor is then the accumulation plus a quarter of the charge. The shipped t_f is 1 s after the first refill.

WHAT IS NOT MODELLED: as batch26 and batch27 (no vapour phase, no decomposition, the reactor's volume held at its declared value – the rate is first order in B, so V does not enter the extent rate).

recipes

The theory you need. A recipe is time-triggered discrete control over batch units: charge, heat/cool, hold, transfer, sample. Between events the DAE integrator runs; at each event the state jumps (a transfer moves holdup between vessels). Expect exact event times on the trajectory and holdup bookkeeping that conserves mass across transfers.

recipe01_react_then_distill

tutorials/batch/recipes/recipe01_react_then_distill

What it does: Two-vessel batch recipe: esterify (AcOH + EtOH → EtOAc + H2O) in a reactor, transfer the charge to a still, then distil

The story: the canonical 2-stage batch recipe.

Stage 1 (t = 0 → 400 s): A batch reactor at 350 K esterifies ethanol + acetic acid → ethyl acetate + water (the same first-order Arrhenius reaction as batch01). k ≈ 3.58e-3 s?[1] at 350 K, tau ≈ 280 s. Over 400 s the ethanol conversion reaches ~76 %.

Stage 2 (t = 400 → 1200 s): The recipe TRANSFERs the reactor contents to an initially empty batch still. The still then runs a Rayleigh distillation at F_vap = 2.0e-5 kmol/s for 800 s, vaporising 0.016 kmol (~85 % of the charge) – the condensed distillate is routed, step by step, into a passive batchAccumulator ('dischargeTo receiver;'), so the campaign ends with the ester-rich distillate IN a vessel while the ethanol-depleted residue stays in the still's own pot (the pot IS the bottoms tank; no third transfer needed). Mass is conserved across the three vessels at every accepted step. Starting from the converted mix (ethyl acetate + water + unreacted ethanol/acid), the still progressively strips the more volatile ethyl acetate + ethanol; pot composition follows the Raoult y-x curve. (The thermoPhysPropDict here uses ideal Raoult for pedagogical simplicity.)

This case demonstrates the recipe layer (v0.23): a list of time-triggered events acting on named units. Each event in the 'recipe' block below has a 'time', an 'action', and action-specific keys. Actions implemented in v0.23:

transfer move all contents of 'from' into 'to' setParameter change a named operating parameter on a unit

Events fire at the next time-loop step boundary after t_trigger; the trajectory CSV thus shows a single-step discontinuity in the transferred quantities.

What to expect (golden-locked):

recipe02_setpoint_ramp

tutorials/batch/recipes/recipe02_setpoint_ramp

What it does: Single-reactor recipe with T_setpoint steps: 320 K → 350 K @ 200 s → 380 K @ 500 s

The story: isothermal batch reactor with a staged temperature programme controlled by the recipe layer.

The reactor starts at 320 K, where the first-order Arrhenius reaction is very slow (k_320 ≈ 3.7e-4 s?[1], $\tau \approx$ 2700 s). Two recipe events ramp the setpoint upward:

t = 200 s → 320 K → 350 K (k jumps ~10x to 3.58e-3 s?[1]) t = 500 s → 350 K → 380 K (k jumps another ~7x to 0.025 s?[1])

In the trajectory CSV the temperature column shows a clean step-change at each event, and the conversion curve shows the corresponding three regimes:

0 ≤ t < 200 s barely-moving plateau (slow) 200 ≤ t < 500 s visible drop in n_ethanol (moderate) 500 ≤ t rapid quench to full conversion (fast)

Demonstrates the recipe layer's 'setParameter' action without inter-unit transfers, so this is the cleanest possible test of the parameter-change pathway.

What to expect (golden-locked):

recipe03_conditional_partial

tutorials/batch/recipes/recipe03_conditional_partial

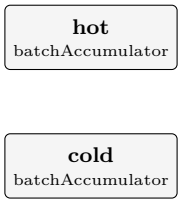
What it does: Conditional + partial recipe: react until x_ethanol < 0.30, then transfer 50% to a still

The story: recipe extensions (v0.50).

Two recipe features beyond the time-triggered transfer/setParameter of v0.23:

1. CONDITION-TRIGGERED event (‘when { ... }‘ instead of ‘time‘): the event fires the first step its condition becomes true, evaluated on the live vessel state. Quantities: T, total, n_<comp>, x_<comp>; operators: gt, ge, lt, le.

2. PARTIAL transfer (‘fraction‘): a fraction (0..1) of the source moves; the source keeps the rest. Default 1.0 == empty the source.



Here the reactor runs the esterification (ethanol + acetic acid → ethyl acetate + water; the batch01 first-order Arrhenius test, k ~ 3.58e-3 s^-1 at 350 K, so n_ethanol = n_ethanol(0).exp(-k t)). The charge is equimolar (x_ethanol starts at 0.5); when the ethanol mole fraction drops below 0.30, the recipe transfers HALF the reactor contents to a still; the reactor keeps the other half and reacts on, while the still distils its charge.

recipe04_charge_enthalpy

tutorials/batch/recipes/recipe04_charge_enthalpy

What it does: H-equality recipe charge: T_mix from the first law, not the molar average; balance CLOSES across a transfer

The story: mixing is a FIRST-LAW act.

Two passive tanks. 'hot' holds 0.5 mol of ethanol at 340 K; 'cold' holds 1.0 mol of water at 300 K. At t = 100 s the recipe empties the hot tank into the cold one. The charge solves the mix temperature from enthalpy equality on the elements datum,

H(n_EtOH + n_W, T_mix) = H(n_EtOH, 340 K) + H(n_W, 300 K),

so heat capacity DIFFERENCES matter: ethanol carries ~112 J/(mol K) against water's ~75, and the enthalpy-true T_mix (~317 K) sits ~4 K above the equal-Cp molar average (313.3 K) a naive mixing rule gives.

Because both species price on the elements datum, no jacket acts, and nothing leaves, the campaign ENERGY BALANCE is AVAILABLE and closes: dH_vessels = 0 to the mix-solve tolerance — the transfer moved enthalpy between tanks without creating or destroying any.

still

The theory you need. A batch still is Rayleigh distillation: $\mathrm{d}(n\,x_i)/\mathrm{d}t = -\dot{V}\,y_i$ with y_i in equilibrium with the pot – the pot composition DRIFTS as the light component leaves (contrast the steady column, where stages hold profiles constant). Expect the distillate to start rich and fade, and the recipe layer (charge, heat, switch receivers) to drive the run. *Full derivation: Theory Guide, the batch-distillation section.*

still01_benzene_toluene

tutorials/batch/still/still01_benzene_toluene

What it does: Rayleigh batch distillation: benzene/toluene 50/50, 1 atm, ideal Raoult

The story: Rayleigh batch distillation, ideal Raoult.

Pot starts with 1 mol of equimolar benzene/toluene at 1 atm. A constant vapour offtake F_vap = 1.5e-6 kmol/s strips the pot over 600 s — by linear mass balance the pot should hold

i.e. L(600 s) = 1 mol - 0.9 mol = 0.1 mol (90 % distilled).

Benzene is the more volatile component (alpha ~ 2.4 at 1 atm), so the still pot progressively concentrates in toluene as benzene flashes off preferentially. Classical Rayleigh integration with constant alpha gives the closed form

ln(L / L_0) = (1 / (alpha - 1)) [ln(x / x_0) + alpha ∗ ln((1 - x_0) / (1 - x))]

where x = x_benzene in the still pot. Plotting (L/L_0) vs x_pot from trajectory.csv should track this analytical curve to RK4 precision.

One mole of 50/50 benzene/toluene in a pot at 1.013 bar, boiled off for 600 s with the vapour taken away as it forms — no reflux, no trays: the Rayleigh equation integrated in time. The pot starts at its bubble point, 365.00 K, and ends at 380.04 K with 0.1 mol left in it at 91.8 % toluene; 0.9 mol (0.0760 kg) has left as distillate. The reboiler supplied 30.33 kJ, the condenser took 29.39 kJ away.

1. The residue gets heavier, and hotter, because the light one leaves first. The Log tab prints the pot every 20 s: benzene falls faster than toluene, T climbs from 365 to 380 K as the pot approaches toluene's boiling point. That is the Rayleigh curve as numbers. 2. The whole campaign is a ledger. [campaign] mass balance: m0 = 0.0851 kg = mF 0.0091 + external 0.0760 kg, closure 0 — what left the domain is counted, not lost. The energy side closes at 4.6e-16 with two records, reboiler and condenser, each priced at its own service temperature (380.0 K and 365.3 K). 3. The thermodynamics is Raoult, and the caveats say where it is stretched. Benzene's Antoine window ends at 354 K and the pot starts at 365 K; toluene's ends at 380 K and the pot ends at 380.04. Both extrapolations are announced at the moment they happen, on the console, inside the table. 4. Utilities are scheduled in time. reports/utilities/ utilityDemand.csv carries the staircase of steam and cooling-water demand across the 600 s — a peak, not just a total, which is what a batch plant is actually sized on.

Halve endTime: the pot is still half full and barely enriched — most of the separation happens late, when there is little left. Then still04_rectifier_benzene_toluene puts three stages and a reflux over the same pot, and the distillate purity that a Rayleigh still cannot reach appears.

still02_ethanol_water_azeo

tutorials/batch/still/still02_ethanol_water_azeo

What it does: Rayleigh batch distillation: ethanol/water 40/60 with NRTL, residue concentrates in water

The story: Rayleigh batch distillation of a non-ideal binary with an azeotrope.

System: ethanol / water with NRTL, pressure 1 atm. Minimum-boiling positive azeotrope at x_eth ~ 0.894 (mole), T ~ 351.3 K.

Pot starts at x_eth = 0.40 (a "wine"-like feed — well BELOW the azeotrope). Boil-off rate F_vap = 1.5e-6 kmol/s for 600 s consumes 90 % of the pot, leaving a 10 % residue.

Below the azeotrope, gamma_ethanol > 1 and gamma_water ~ 1, so the vapour is markedly richer in ethanol than the liquid (y_eth ~ 0.61 at x_eth = 0.40). Ethanol therefore vaporises preferentially and the still pot progressively concentrates in WATER — i.e. the residue at end-of-run is mostly water.

The pedagogical contrast with still01 (ideal Raoult, benzene/toluene) is the SHAPE of the enrichment curve:

Raoult: smooth, alpha-driven (alpha ~ 2.4, roughly constant). NRTL : curvature changes as x crosses concentration regimes in which gamma_ethanol shrinks toward 1; the still composition curve x_pot(t) is noticeably non-linear vs the linear pot-volume curve L(t) = L_0 - F_vap∗t.

Crucially, this case demonstrates that a single Rayleigh still cannot cross the azeotrope. Starting below 0.894 in ethanol, the pot can only move DOWNWARD in ethanol fraction; no amount of boiling will lift the pot composition past 0.894. (To break the azeotrope one needs entrainer, pressure swing, or extractive distillation — topics for later tutorials.)

still03_with_receiver

tutorials/batch/still/still03_with_receiver

What it does: Rayleigh still distilling INTO a receiver tank (dischargeTo accumulator)

The story: Rayleigh batch distillation INTO a receiver (accumulator vessel + continuous dischargeTo).

Same pot as still01 (1 mol equimolar benzene/toluene, F_vap = 1.5e-6 kmol/s, ideal Raoult), but the still's vapour is no longer lost: the 'dischargeTo receiver;' line routes the condensed distillate, step by step, into a passive 'batchAccumulator'. So the trajectory shows the POT depleting AND the RECEIVER filling — the receiver collects the total distillate (amount + composition). Mass is conserved between the two vessels: pot + receiver = 1 mol at all times. Benzene is the more volatile component, so the receiver is benzene-rich early and the cumulative receiver composition drifts toward 0.5 as distillation nears completion (it ends holding everything the pot lost).

still04_rectifier_benzene_toluene

tutorials/batch/still/still04_rectifier_benzene_toluene

What it does: batch rectification: 3 stages + total condenser, R=3, with receiver tank (dischargeTo accumulator)

The story: the CLASSICAL batch rectification (model rectifier, design forum #85): the Rayleigh pot now feeds a column of 3 ideal stages topped by a total condenser at constant reflux R = 3.

F_vap is the internal BOILUP V = 1.5e-6 kmol/s; the distillate PRODUCT is D = V/(R+1) = 3.75e-7 kmol/s and the reflux L = R.D returns to the column. The pot loses PRODUCT only: dn_i/dt = -D.x_D_i, with x_D(t) solved at every instant from the quasi-steady cascade (stage balances + bubble-T equilibrium + total-condenser closure – a declared residual, printed on failure).

What to watch (trajectory.csv): still.xD_benzene starts ~0.949 (vs ~0.71 for the raw pot vapour – the column working) and DRIFTS DOWN as the pot strips: the constant-R policy trades purity for time. The receiver's ACCUMULATED benzene fraction sits between the instantaneous x_D and the feed – two different compositions, deliberately both visible. The pot loses only D.dt = 0.225 mmol over 600 s (vs 0.9 mmol in still01: same boilup, but 3/4 of it refluxes).

Physics anchors (verified at authoring): x_D(0) grows with nStages and R (N=1,R=1: 0.806; N=2,R=3: 0.909; N=3,R=3: 0.949) and the R → infinity limit (R=200: 0.9765) lands inside the Fenske band alpha^(N+1) for alpha = 2.35-2.6. With nStages 0 and refluxRatio 0 the model reproduces still01's Rayleigh trajectory to the last digit.

still05_rectifier_constant_xD

tutorials/batch/still/still05_rectifier_constant_xD

What it does: batch rectification, constant-composition policy: R(t) holds x_D until refluxMax, then D=0

The story: the SECOND classical reflux policy (design forum #85-3/4): hold the distillate composition constant by RAISING the reflux as the pot strips, and STOP when the declared ceiling can no longer reach the target.

Same pot and column as still04 (1 mol equimolar benzene/toluene, V = 1.5e-6 kmol/s, 3 ideal stages + total condenser), but instead of a fixed R the policy solves R(t) each step – a BRACKETED solve over [0, refluxMax] on a feasibility map, never a bare Newton – so that x_D[benzene] = 0.93 exactly. As benzene depletes, R climbs (~2 at the start); when even refluxMax = 8 cannot reach the target the run announces 'onRefluxLimit stopDistillation': D = 0, the pot stops losing mass, and the campaign idles VISIBLY to endTime with still.refluxLimitReached = 1 in the trajectory – never a magic termination.

What to watch (trajectory.csv): still.xD_benzene pinned at 0.9300 while R climbs – the mirror image of still04, which held R and let purity drift; still.R rising 2.0 → 8 (the ceiling), then the limit event; the receiver's accumulated composition ~0.93 (the whole cut is on-spec – THE selling point of this policy); pot inventory constant after t_refluxLimit.

Declared refusals (each with its own diagnostic, try them): x_D_target 0.5 → BELOW the R=0 floor (even zero reflux over-purifies); x_D_target 0.995 with refluxMax 5 → UNREACHABLE from the charge; ethanol/water NRTL with x_D_target 0.95 → the 0.894 azeotrope caps the cascade at ANY reflux (the barrier is real VLE, not a message).

still06_ledger_mixed_validity

tutorials/batch/still/still06_ledger_mixed_validity

What it does: Ledger H-validity is MONOTONIC: mixed valid/invalid packages never resurrect a poisoned record

The story: MONOTONIC enthalpy validity on the material ledger (the adversarial case of design forum #99/#101).

The campaign ledger integrates each transfer's enthalpy PACKAGE BY PACKAGE at each package's own temperature. A package containing a species with NO formation datum (here 'compA', a lumped teaching species that deliberately carries no standardThermochemistry block) cannot be priced — the record must mark H invalid and NAME the species. The contract under test is the temporal one:

once ONE package is unpriceable, the record's integrated H has lost a parcel FOREVER. Validity is MONOTONIC: a later priceable package must never resurrect it.

Two stills exercise the two orders on ONE accumulated record each:

potA (invalid → valid): starts with 10 % compA, so its distillate record potA→recA begins UNPRICEABLE. At t = 200 s the recipe dumps the whole pot to 'dump' and recharges clean benzene/toluene from 'fresh'; every later distillate package is priceable. The record must STAY invalid (H_missing = compA), and the discrete potA→dump record is invalid too (it carried the compA).

potB (valid → invalid): starts clean, so its distillate record potB→recB begins priceable and accumulates real enthalpy. At t = 200 s the recipe spikes it with pure compA from 'spike'; every later package is unpriceable. The record flips invalid and the partial integral is WITHHELD — an emitted H_kJ that silently lost its tail would be a lie.

Five ledger records result: potA→recA (continuous, poisoned early), potB→recB (continuous, poisoned late), potA→dump and spike→potB (discrete, carrying compA: unpriceable), fresh→potA (discrete, clean: the ONE priceable record). The golden pins the campaign census transfers_H_valid = 1 / transfers_H_invalid = 4; the results JSON carries H_missing = [compA] and NO H_kJ key on every poisoned record.

Category V: Dynamics and control (choupoCtrl)

Continuous processes in time with feedback: PID loops, setpoint schedules, disturbances and responses.

ctrl01_cstr_temp_control

tutorials/ctrl/ctrl01_cstr_temp_control

What it does: Dynamic CSTR (compA → compB) with PID jacket-temperature control; T climbs from 320 K into the +/-2% setpoint band within ~20 s (no overshoot) and tracks toward 350 K across the 150 s window

The story: the canonical first choupoCtrl test.

Process: Continuous CSTR with first-order reaction compA → compB – an ISOMERISATION: both stand-ins carry MW 30, so the pseudo-reaction conserves mass exactly and the run-end material ledger closes to machine precision. (The element balance stays honestly UNAVAILABLE: compA/compB are numerical stand-ins with no real formula, and the ledger says so by name instead of fabricating atoms.) Feed is pure compA at 320 K, 5×10?? kmol/s; reactor volume 1 L; mild exotherm (ΔH_rxn = -50 kJ/mol). Without control the reactor settles a few K above the inlet temperature (small reaction exotherm balanced by convective cooling), well below the desired setpoint of 350 K.

Controller: A PID acts on the jacket temperature (T_jacket) to drive the reactor temperature (T) to a setpoint of 350 K. Tuning is pedagogical, not optimal:

Kp = 4.0 (proportional band ≈ 7-8 K) Ki = 0.04 (integral time τ_I = Kp/Ki ≈ 100 s) Kd = 0.0 (no derivative; system is benign enough)

Jacket bounded to [280, 420] K — realistic limits of a utility loop. Anti-windup: integral does not advance when the unclamped output is outside the bounds.

Expected trajectory (150 s window): Open-loop: T relaxes a few K above the 320 K inlet (small exotherm balanced by convective cooling). Closed-loop: T rises fast (the jacket MV slams to its 420 K clamp, then backs off), entering the +/-2% setpoint band by ~ 20 s, well-damped with no overshoot. By 150 s T is ~ 348.5 K and still creeping up: the last ~ 1.5 K rides the slow chemical tail (the exotherm's conversion, tau ~ 120 s) toward 350 K beyond the window. The jacket (MV) settles around 348.5 K to keep heating in against the cool 320 K feed. (Widen endTime to watch the final approach to 350 K; the 150 s window is sized to SHOW the control transient, not the slow tail.)

To run the OPEN-LOOP comparison, comment out the entire 'controllers' block below — the case will then run the bare reactor with whatever T_jacket the 'operation' block initialised it to (here 320 K, i.e. no jacket heating).

A 1-litre continuous stirred reactor with a first-order A → B reaction (two stand-in components, both MW 30 — the pseudo-reaction says so by name rather than inventing atoms), fed at 320 K, with a jacket whose temperature a PID controller sets to hold the reactor at 350 K. 150 s of transient, 1 s steps. The golden: PV ends at 348.47 K, the jacket (MV) at 348.54 K, mass in = out = 0.225 kg over the run and the material balance closes at 1.8e-15.

1. The controller is a unit in the dict, with its tuning in the open. type PID; setpoint 350.0; gains { Kp 4.0; Ki 0.04; Kd 0.0; } output { min 280; max 420; bias 320; } — proportional band ≈ 7–8 K, integral time τ_I = Kp/Ki = 100 s, no derivative. Nothing is tuned for you. 2. Watch the manipulated variable saturate. At t = 2 s the jacket demand jumps to the 420 K clamp (the log's last column), then backs off as the reactor warms: 402, 385, 374 K ? The Log tab prints every 2 s; the clamp is a number in the dict and you can see it bind. 3. Into the band, then the slow part. The reactor crosses 343 K — the -2 % edge of the setpoint band — at t ≈ 14 s. At 150 s it sits 1.5 K under setpoint and still climbing: that is the integral action at τ_I = 100 s working off the offset. Widen endTime and watch it arrive. 4. The energy balance REFUSES here, and says why. [balance] energy: UNAVAILABLE — the dynamicCSTR energy equation is a Cp/convective model, not the exact derivative of a stored H. The stand-in components carry no formation enthalpy on purpose; a ledger that cannot be exact says so rather than printing a closure it did not earn. ctrl11 is the case where it can, and does (1.4e-7).

Set Kp 8.0;: faster into the band, more overshoot, the clamp held longer. Then Ki 0; — the offset never closes, which is what a proportional-only loop teaches in one run. ctrl02_disturbance_rejection steps the feed temperature and asks the same loop to hold.

ctrl02_disturbance_rejection

tutorials/ctrl/ctrl02_disturbance_rejection

What it does: PID disturbance rejection: T_in steps down then up, PID maintains T_setpoint

The story: the textbook control demo.

Same DynamicCSTR as ctrl01 (compA → compB, mild exotherm, jacket heat transfer). Same PID temperature controller. Two added ingredients:

1. The simulation runs 2000 s (long enough to reach steady state after each disturbance). 2. A second "controller" of type Schedule injects step disturbances in the inlet temperature T_in:

0 | 320 (nominal) 700 | 305 (-15 K cold disturbance) 1300 | 335 (+15 K warm disturbance, back-and-up)

The PID controller has no foreknowledge of these disturbances — it only sees T_reactor drift away from setpoint and acts on the jacket to compensate. Expected behaviour:

$0 < t < 700$: normal startup, T → 350 K (≈ ctrl01). $t = 700$: T_in drops 15 K; the integral action absorbs it so tightly that T_reactor holds at 350 K with no visible sag (the jacket simply keeps heating). $t = 1300$: T_in rises 15 K; again T_reactor stays pinned at 350 K with no visible deviation.

The trajectory.csv columns now include both controllers' SP / PV / MV. The Schedule controller's SP and MV mirror the same step train (it has no PV); the PID's SP stays at 350 K and its PV (T_reactor) tracks closely.

ctrl03_adaptive_disturbance

tutorials/ctrl/ctrl03_adaptive_disturbance

What it does: PID disturbance rejection with ADAPTIVE plant integration — controller samples on the fixed 1 s grid, Rosenbrock23 sub-steps between samples (MV held)

The story: the ctrl02_disturbance_rejection demo re-integrated with an ADAPTIVE plant integrator: the PID still samples on the fixed 1 s control grid (MV held between samples) while Rosenbrock23 sub-steps the plant adaptively in between. The flowsheet below is ctrl02's textbook disturbance-rejection setup, unchanged:

Same DynamicCSTR as ctrl01 (compA → compB, mild exotherm, jacket heat transfer). Same PID temperature controller. Two added ingredients:

1. The simulation runs 2000 s (long enough to reach steady state after each disturbance). 2. A second "controller" of type Schedule injects step disturbances in the inlet temperature T_in:

0 | 320 (nominal) 700 | 305 (-15 K cold disturbance) 1300 | 335 (+15 K warm disturbance, back-and-up)

The PID controller has no foreknowledge of these disturbances — it only sees T_reactor drift away from setpoint and acts on the jacket to compensate. Expected behaviour:

$0 < t < 700$: normal startup, T → 350 K (≈ ctrl01). $t = 700$: T_in drops 15 K; the integral action absorbs it so tightly that T_reactor holds at 350 K with no visible sag (the jacket simply keeps heating). $t = 1300$: T_in rises 15 K; again T_reactor stays pinned at 350 K with no visible deviation.

The trajectory.csv columns now include both controllers' SP / PV / MV. The Schedule controller's SP and MV mirror the same step train (it has no PV); the PID's SP stays at 350 K and its PV (T_reactor) tracks closely.

ctrl05_disturbance_transient

tutorials/ctrl/ctrl05_disturbance_transient

What it does: PID disturbance rejection with OpenFOAM-style real-time instant dirs: T_in steps down (700 s) then up (1300 s); scrub 0/ 40/ 80/ ... s to watch the PID track the 350 K setpoint and the jacket MV move

The story: the textbook control demo, captured in OpenFOAM-style real-time instant directories (see controlDict's solutionControl block). Identical physics to ctrl02; the difference is that each written time directory (the layout of 0/: the holdup under '<t>/internalStates/', one file per stream) can be scrubbed across the two disturbance steps to watch the PID reject them.

Same DynamicCSTR as ctrl01 (compA → compB, mild exotherm, jacket heat transfer). Same PID temperature controller. Two added ingredients:

1. The simulation runs 2000 s (long enough to reach steady state after each disturbance). 2. A second "controller" of type Schedule injects step disturbances in the inlet temperature T_in:

0 | 320 (nominal) 700 | 305 (-15 K cold disturbance) 1300 | 335 (+15 K warm disturbance, back-and-up)

The PID controller has no foreknowledge of these disturbances — it only sees T_reactor drift away from setpoint and acts on the jacket to compensate. Expected behaviour:

$0 < t < 700$: normal startup, T → 350 K (≈ ctrl01). $t = 700$: T_in drops 15 K; the integral action absorbs it so tightly that T_reactor holds at 350 K with no visible sag (the jacket simply keeps heating). $t = 1300$: T_in rises 15 K; again T_reactor stays pinned at 350 K with no visible deviation.

ctrl06_sine_disturbance

tutorials/ctrl/ctrl06_sine_disturbance

What it does: Forced SINUSOIDAL inlet-T disturbance: T_in = 320 + 15 sin(2 pi t / 600). The PID chases a moving target → the reactor temperature settles into a forced sinusoidal response (attenuated + phase-lagged). Sweep the period to build a one-point Bode by trial-and-error (the frequency-response seed).

The story: the FREQUENCY-RESPONSE seed.

Same DynamicCSTR as ctrl01/ctrl02 (compA → compB, mild exotherm, jacket heat transfer) and the same PID temperature controller. The NEW ingredient is the disturbance: instead of the step train of ctrl02's 'Schedule' controller, a 'Signal' controller injects a SINUSOID into the inlet temperature T_in:

T_in(t) = 320 + 15 ∗ sin(2∗pi∗t / 600) [K]

mean = 320 K amplitude = 15 K period = 600 s (f = 1/600 = 1.667e-3 Hz, omega = 0.01047 rad/s)

The PID controller has no foreknowledge of the forcing — it only sees T_reactor drift sinusoidally away from the 350 K setpoint and works the jacket to compensate. After the first ~period the reactor temperature settles into a FORCED SINUSOIDAL RESPONSE: same period as the input, but ATTENUATED (the closed loop rejects most of the swing) and PHASE-LAGGED.

THE LESSON (Seborg/Edgar/Mellichamp/Doyle, Ch. 13-14 frequency response): read the output/input amplitude ratio [dB] and the phase lag [deg] off the steady-cycling trajectory, and you have ONE POINT of a Bode plot. Sweep the 'period' (edit one number below), re-run, and you trace the closed loop's frequency response by trial-and-error — the differentiator.

Backward-compatible by construction: ctrl02's 'type Schedule; schedule(...)' staircase still works unchanged; this case swaps it for the more general 'type Signal; signal { type sinusoidal; ... }'.

ctrl07_lhhw_inhibition

tutorials/ctrl/ctrl07_lhhw_inhibition

What it does: Product inhibition meets a PID: an LHHW reaction whose exotherm fades as its own product covers the catalyst

The story: ctrl01's temperature loop, with a reaction that poisons itself.

Same vessel, same PID, same setpoint. The one change is the rate law: the product compB now ADSORBS on the catalyst, so the denominator grows as the reaction proceeds,

r = k(T) . c_A / (1 + K_B c_B)

and the reaction throttles itself. A power law cannot express that at any order; only the adsorption term can. This is the same 'RateLaw' that the steady 'cstr' and the 'batchReactor' evaluate – one definition, three reactors.

What the controller sees: an exotherm that FADES as conversion proceeds, not a constant one. The heat the loop is rejecting shrinks under it, and the jacket temperature must follow. A tuning that holds against a first-order exotherm is not the same tuning that holds against a decaying one.

The adsorption constant K0 = 2.0 m^3/kmol is DIDACTIC – chosen so the inhibition is visible over the control horizon, not measured on any catalyst. For a real, cited LHHW see 'cstr07_lhhw_methylAcetate' and 'batch07_lhhw_methylAcetate' (Popken 2000, Eq 16, on UNIQUAC activities).

ctrl08_prbs_ident

tutorials/ctrl/ctrl08_prbs_ident

What it does: PRBS identification experiment: T_in = 320 +/- 10 K by a maximal-length LFSR (n=4, period 15 bits x 120 s) – deterministic, seed-declared, period-VERIFIED; the broadband excitation the sine of ctrl06 cannot give.

The story: PRBS identification experiment (forum #100.4/#101).

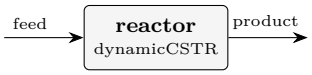
The classic system-identification input: a pseudo-random binary sequence on the inlet temperature, T_in = 320 +/- 10 K, driven by a MAXIMAL-LENGTH Fibonacci LFSR — n = 4 registers, canonical taps (4 3), DECLARED seed 1, period 2^4 - 1 = 15 bits of 120 s each (1800 s per full period).

Why a PRBS and not ctrl06's sine: one sinusoid excites ONE frequency; the PRBS is broadband (its autocorrelation approximates an impulse), so a single record carries the information for a full low-order model fit. And unlike real "random" noise it is DETERMINISTIC: seed + taps declared in this dict reproduce the experiment bit for bit, run after run.

THE HAND-DERIVED SEQUENCE (the exact-sequence contract of #101): with the frozen convention (output = s_n; feedback = XOR of taps; shift s_1 <- feedback; seed LSB → s_1), n=4 / taps (4 3) / seed 1 gives

0 0 0 1 0 0 1 1 0 1 0 1 1 1 1 (bits k = 0..14, then repeats)

– walk it yourself: state 0001 → 0010 → 0100 → 1001 → 0011 → 0110 → 1101 → 1010 → 0101 → 1011 → 0111 → 1111 → 1110 → 1100 → 1000 → 0001 (back at the seed after EXACTLY 15 steps: maximal). The run's announce line prints these same first bits; the initialiser REFUSES any tap set whose cycle is not exactly 2^n - 1.



The PID (same tuning as ctrl06) holds the reactor at 350 K against the binary disturbance; the trajectory's T_in column IS the PRBS, and the reactor response is the identification record.

What to expect (golden-locked):

ctrl09_stream_disturbance

tutorials/ctrl/ctrl09_stream_disturbance

What it does: Inlet-field disturbance: componentMolarFlow.compA steps 3.5e-5 → 5.25e-5 kmol/s; F and z_in change by the DERIVED values (F = 6.75e-5, z_A = 7/9) – the disturbance never hides from the other components

The story: the inlet-field actuator, end to end.

The Signal controller targets the reactor's INLET FACE by field name ('inletField componentMolarFlow.compA') — the only legal disturbance surface (an outlet actuator is not even expressible). The AUTHORITATIVE inlet state is the per-component molar-flow vector; F_in and z_in are DERIVED from it on every write, so a composition disturbance can never hide inside a silent renormalisation (forum #101):

t < 600 s: nA = 3.5e-5, nB = 1.5e-5 kmol/s → F_in = 5.0e-5, z_A = 0.70, z_B = 0.30 t >= 600 s: nA stepped to 5.25e-5; nB UNTOUCHED at 1.5e-5 → F_in = 6.75e-5, z_A = 5.25/6.75 = 7/9 = 0.77778, z_B = 1.5/6.75 = 2/9 = 0.22222 (hand-derived)

The golden pins F_in and z_in_* finals to these fractions, and the Signal value is the ABSOLUTE molar flow (announced at start-up). The reactor's own response (more A in, higher conversion load, T transient against the PID) is the pedagogy; the CONTRACT is the derived pair.

The 'moleFraction.<c>' sibling field instead holds F_in constant and renormalises the OTHER components proportionally — two explicit semantics, each announced, never a guess.

What to expect (golden-locked):

ctrl10_brine_concentration

tutorials/ctrl/ctrl10_brine_concentration

What it does: Dynamic brine tank on a Pitzer package: the electrolyte thermodynamics through a transient

The story: ONE stirred vessel, NO reaction. The dynamic CSTR tolerates an empty reaction list, and that is exactly the model wanted here: the holdup is a mixing lag, and the thermodynamics – Pitzer activity coefficients on the molality basis – is what travels through it.

The jacket loop is the same PID shape as ctrl01: it acts on T_jacket to hold the vessel temperature. A brine tank held on temperature is what sits upstream of every evaporator and crystalliser in the corpus.

What to expect (golden-locked):

kind	unit/stream	key	expected

ctrl11_esterification_jacket

tutorials/ctrl/ctrl11_esterification_jacket

What it does: Jacketed esterification CSTR under PID temperature control: the first ctrl case whose stored enthalpy exists, so the first-law ledger claims closure instead of refusing

The story: One jacketed vessel and one PID loop – the same shape as ctrl01, so the two can be read side by side. What differs is the chemistry: real species with a formation datum instead of numerical stand-ins, which is the whole reason this case can carry an energy claim and ctrl01 cannot.

The reaction declares NO dH_rxn. On the elements datum the heat of reaction is Sum(nu_i h_i(T)) – a consequence of the same enthalpy surface the vessel stores, not a second number to keep in step with it.

What to expect (golden-locked):

kind	unit/stream	key	expected
kpi	TC1	MV_final	366.642237189

kpi	plant	t_end	720000

. . . and 8 more reference values in the case's `expected`.

ctrl14_williams_otto_pi

tutorials/ctrl/ctrl14_williams_otto_pi

What it does: Williams-Otto PI channel (F_fB, F_pP), paper eq. 4.6 with the section-4.1 tunings: F_pP tracks 3.90 → 4.5 klb/h with the Fig. 4 overshoot

The story: One unit, because the benchmark IS one equation set: the Williams-Otto reactor + decanter + column + splitter fold into six ODEs (the recycle term (1-eta)mu, the removed G, the 0.1 F_tE column retention are all inside them – see the unit's own header). The five controls sit in 'operation', declared SI: with the MW 453.592 convention (1 kmol == 1 klb) every numeral below IS the paper's value in klb/h.

The paper's control channel (F_fB, F_pP), eq. (4.6), with the Skogestad-IMC gains of section 4.1: K3prop = 0.069 (dimensionless – klb/h per klb/h survives the SI conversion unchanged) and K3int = 1.282 per HOUR, declared per second (1.282/3600 = 3.5611111e-4). Bias = F∗_fB (bumpless), setpoint F_pP = 4.5 klb/h = 1.25e-3 kmol/s, output bounded to the paper's 0 <= F_fB <= 56 klb/h.

ctrl17_step_reaction_curve

tutorials/ctrl/ctrl17_step_reaction_curve

What it does: Open-loop process reaction curve: the jacket steps +5, -5, +20 and -20 K from one settled base, and the four responses are the identification record for the FOPDT fit in system/propsDict

The story: THE IDENTIFICATION, run over the trajectory the choupoCtrl half of this case wrote. Run the experiment first:

runCase tutorials/ctrl/ctrl17_step_reaction_curve choupoProps tutorials/ctrl/ctrl17_step_reaction_curve

Each operation DECLARES that its trajectory is the process run's (‘writtenBy { trajectory process; }‘), so the second command run alone, on a fresh copy, refuses by name and says to run the first.

TWO OPERATIONS OVER ONE EXPERIMENT, and the pair is the lesson. Both read the SAME four steps of the SAME jacket temperature; they differ only in which response they call the controlled variable.

[0] the COMPOSITION loop (jacket → product holdup). Two lags in series – the jacket heats the liquid, and the warmer liquid reacts faster – so the response is S-shaped and an FOPDT surrogate finds a real apparent dead time. All three tuning rules apply.

[1] the TEMPERATURE loop (jacket → reactor temperature). One dominant lag and no transport delay, so the identified theta comes out smaller than the trajectory's own sampling interval. The engine says so, and REFUSES every Ziegler-Nichols and Cohen-Coon setting by name: both rules put theta in a denominator, and a controller gain computed from an unresolved number is a number with nothing behind it. IMC survives, because its algebra never divides by theta – which is exactly why it is the rule of choice for a lag-dominant loop.

Nothing was tuned to make that happen. It is one plant, one experiment, and two honest answers, and the difference between them is the whole reason the reaction-curve method needs a dead time to work at all.

What to expect (golden-locked):

ctrl18_rtd_pulse_cstr

tutorials/ctrl/ctrl18_rtd_pulse_cstr

What it does: RTD by pulse tracer on a pure mixing tank: tracer substitution at constant flow, tau = N/F = 240 s; engine-measured moments against Levenspiel closed-form anchors.

The story: RESIDENCE-TIME DISTRIBUTION by pulse tracer – the engine's first RTD tool (2026-08-23). A pure mixing tank (the ctrl09 vessel, reaction and controller stripped) holds N = 0.012 kmol and is fed F = 5e-5 kmol/s, so tau = N/F = 240 s exactly. For 30 s starting at t = 100 s the feed SWAPS 1e-5 kmol/s of carrier for tracer – compB pulses up by exactly what compA pulses down – so the total flow never moves and the vessel is rigorously linear and time-invariant in the tracer.

THE ANCHORS ARE CLOSED FORMS (Levenspiel, Chemical Reaction Engineering, ch. 13-14 – moment additivity of a linear vessel, exact for ANY inlet shape): tbar_out = tbar_in + tau = (100 + 15) + 240 = 355 s sigma2_out = sigma2_in + tau^2 = 30^2/12 + 240^2 = 57675 s^2 area = amplitude x width = 1e-5 * 30 = 3.0e-4 kmol The engine measures the outlet response moments (rtd KPIs, trapezoid on the accepted-step grid, reports/rtd/E.csv); the arithmetic above is the case's, stated here. Deviations from the anchors are integration truncation (run = 2600 s ~ 10.4 tau past the pulse; e^-10.4 ~ 3e-5) plus the finite step – both stated, neither hidden.

What to expect (golden-locked):

kind	unit/stream	key	expected

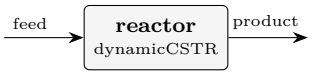
ctrl19_freq_response_cstr

tutorials/ctrl/ctrl19_freq_response_cstr

What it does: Frequency response of the LTI mixing tank at omega∗tau = 1: engine-fitted amplitude and phase against the exact first-order closed forms (AR = 1/sqrt(2), phase = -45 deg).

The story: FREQUENCY RESPONSE of the same LTI mixing tank (tau = N/F = 240 s): the tracer feed oscillates sinusoidally at omega∗tau = 1 – again as a SUBSTITUTION against the carrier, so total flow never moves and the vessel is rigorously first order in the tracer. The engine fits a + b sin + c cos over 4 cycles after discarding 5 (transient e^-t/tau through 5 periods = e^-31 – gone), and reports amplitude, phase and the unexplained-variance residual.



THE ANCHORS ARE THE FIRST-ORDER CLOSED FORMS (any process-control text; at omega∗tau = 1 exactly): AR = 1/sqrt(1 + (omega tau)^2) = 1/sqrt(2) → out amplitude = 2.0e-6 ∗ 0.7071068 = 1.4142136e-6 kmol/s phase = -atan(omega tau) = -45 deg = -0.7853982 rad (the drive is sin(w(t-tStart)) with tStart 0, so the fitted phase IS the lag). The measured amplitude lands within 1e-6 relative of the closed form and the fit residual is ~7e-15 (the vessel really is LTI); the phase carries a bias of EXACTLY omega∗dt/2 = 0.00208 rad = 0.12 deg – the half-sample lag of reading accepted states on a 1 s grid, the measurement system's own phase contribution, worth teaching in itself. The anchor band covers it and this header names it.

ctrl20_bode_cstr

tutorials/ctrl/ctrl20_bode_cstr

What it does: Bode table of the LTI mixing tank: outer frequency sweep (one datum, lockstep mirror) over the engine frequency-response fit; anchors are the exact first-order closed forms at each point.

The story: THE BODE TABLE of the LTI mixing tank (tau = 240 s): an outer sweep drives the sinusoidal tracer substitution at four frequencies, omega∗tau = 0.5, 2.0, 3.5, 5.0 (linear grid in f), and the engine's frequencyResponse fit measures amplitude and phase at each – the sweep CSV IS the Bode table. The measurement block references the drive, so each pass's fit window adapts to that pass's own period, and the sweep varies ONE datum (the drive frequency, mirrored to the carrier by linkedTargets – the same value, lockstep, never a second independent number).

ANCHORS: the exact first-order closed forms at each grid point, AR = 1/sqrt(1+(wt)^2), phase = -atan(wt): wt=0.5: |out| = 2e-6∗0.894427 = 1.788854e-6, phi = -0.463648 rad wt=2.0: |out| = 2e-6∗0.447214 = 8.944272e-7, phi = -1.107149 rad wt=3.5: |out| = 2e-6∗0.274721 = 5.494423e-7, phi = -1.292497 rad wt=5.0: |out| = 2e-6∗0.196116 = 3.922323e-7, phi = -1.373401 rad Phase bands cover the omega∗dt/2 half-sample bias, which grows with omega (0.10 to 1.0 mrad here) – stated, not hidden.

ctrl21_tank_level_control

tutorials/ctrl/ctrl21_tank_level_control

What it does: Water tank with a manipulated outflow and a PI level controller: the inflow steps +50 % at 600 s, the integrating level is brought back to the 2.0 m setpoint (P-only would settle 0.05 m off)

The story: the most common loop of a plant: INVENTORY.

The same water tank as unsteady05 (D = 2 m, area 3.1416 m2), but its outflow is a MANIPULATED FLOW (a flow-controlled pump: 'mode flow', mv F_out), so the level INTEGRATES the difference of the flows,

A rho/MW dh/dt = F_in - F_out plant gain a = MW/(rho A) = 5.7e-3 m/s per kmol/s (rho = 1001.55 kg/m3)

and nothing brings it back: an integrating process. A level controller closes the loop on F_out. The inflow steps at t = 600 s from 0.20 to 0.30 kmol/s (a Signal on the tank's inlet face).

THE SIGN. The controller is direct-acting on error = setpoint - level, and a level ABOVE the setpoint must RAISE the outflow, so the gains are NEGATIVE (u = bias + Kp (SP - h) + Ki Int(SP - h) with Kp < 0). Bias 0.20 kmol/s is the outflow that balances the old inflow.

WHAT THE TWO CONTROLLERS DO (measured; check_dynamic_tank re-runs both):

PI (Kp = -2, Ki = -0.01): the integral term removes the offset; the level returns to the 2.0 m setpoint (zero offset), after a peak excursion of 0.031 m (max |h - 2| in trajectory.csv; the end offset is < 1e-7 m). P-only (Ki = 0, edit one line): the outflow must rise by 0.10 kmol/s and a proportional-only controller can only do that with an error, F_out = bias + Kp (SP - h) → h - SP = (F_in,new - bias)/|Kp| = 0.10 / 2 = 0.050 m (offset: the level settles at 2.05 m).

The closed loop is second order, wn^2 = a |Ki| , 2 zeta wn = a |Kp|: wn = 7.6e-3 1/s, zeta = 0.76. The inflow is a disturbance the loop must reject; the tank's own buffering (volume) is what the controller trades against the downstream flow's smoothness – loose level control is a feature, not a defect, when the outflow feeds another unit.

ENERGY. H on the elements datum, T a readout; the ledger claims mass and energy and closes (check_dynamic_tank).

A water tank (dynamicTank, D = 2 m, 3.14 m^2) whose outflow is a manipulated flow (mode flow, mv F_out, a flow-controlled pump). Because nothing in the outflow depends on the level, the level integrates the difference of the flows and never comes back by itself. A PI level controller on F_out closes the loop. The inflow steps from 0.20 to 0.30 kmol/s at t = 600 s; 3000 s run, 2 s steps.

Run it: runCase tutorials/ctrl/ctrl21_tank_level_control (it runs under choupoCtrl). Its sibling unsteady05_tank_valve_drain drains the same tank through a valve instead and needs no controller.

1. The PI holds the level. Plot level in trajectory.csv: it stays at the 2.0 m setpoint, rises by at most 0.031 m after the inflow step and returns with zero offset (< 1e-7 m at the end). The integral term is what removes the offset. 2. P-only settles off the setpoint. Set Ki 0.0; in the controller's gains {} and run again: the level ends at 2.05 m. A proportional controller needs an error to hold a different outflow, and the offset is (F_in,new - bias)/ = (0.30 - 0.20)/2 = 0.050 m. 3. The gains are negative. The controller is direct-acting on error = setpoint - level; a level ABOVE the setpoint must RAISE the outflow, so the loop is reverse-acting and Kp, Ki are negative. With a positive sign the level runs away until the tank overflows, and the engine refuses that by name (OVERFLOWED). 4. The ledger claims mass and energy and closes (~1e-14): the tank stores its enthalpy on the elements datum, T is a readout. [balance] lines print the check.

The closed loop is second order (?n ≈ 7.6e-3 1/s, ? ≈ 0.76). The tank's buffering is what a loose level loop trades against the smoothness of the downstream flow. check_dynamic_tank re-runs both the PI and the P-only variants and holds these numbers.

ctrl22_reactor_level_and_temperature

tutorials/ctrl/ctrl22_reactor_level_and_temperature

What it does: Reactor with a level: a PI level loop on the outflow and a PI temperature loop on the jacket act on ONE unit while the inflow steps +50 % – the level returns to its setpoint, the temperature holds, the jacket area follows the liquid

The story: A jacketed reactor with a LEVEL (dynamicCSTR, 'volumeMode variable', C205 slice 2): isobutanol → 2-butanol, first order, exothermic, fed at 300 K and run at 340 K. Its outflow is a MANIPULATED FLOW (as in ctrl21), so the level INTEGRATES the flow imbalance and needs a controller; its temperature is held by the jacket (as in ctrl01). The two loops act on different manipulated variables of the same vessel:

LC1 PI cv level → mv F_out reverse acting (Kp, Ki < 0) TC1 PI cv T → mv T_jacket direct acting on the error T_SP - T

and they are COUPLED through the vessel, which is the lesson:

the level sets the volume, so the jacket's wetted area – the declared UA is the value with the vessel FULL, UA(h) = UA A_w(h)/A_w(H) with A_w = pi D h + pi D^2/4 – and the reaction heat r V both follow it; the outflow leaves at the vessel's temperature, so it carries enthalpy away; the canonical energy route (announced at start-up) lets that term cancel exactly, and the ledger closes for the whole run.

The inflow steps from 1.0e-3 to 1.5e-3 kmol/s at t = 1200 s (a Signal on the inlet face). Level plant gain a = v/A = 0.47 m per kmol (liquid molar volume 0.093 m3/kmol over 0.196 m2); with wn = 0.01 1/s, zeta = 0.8 the PI gains are Kp = -2 zeta wn / a = -0.034, Ki = -wn^2 / a = -2.1e-4 kmol/s per m(s). Bias 1.0e-3 kmol/s is the outflow that balances the old inflow.

The cold feed lowers the temperature as the inflow rises; the jacket absorbs it. Read trajectory.csv: 'level', 'T', 'F_out', 'volume', and the controllers' MV columns.

A jacketed reactor with a level (dynamicCSTR with volumeMode variable, D = 0.5 m, H = 1.0 m): isobutanol → 2-butanol, first order, exothermic, fed at 300 K and run at 340 K. Two PI controllers act on DIFFERENT manipulated variables of the SAME vessel:

∗ LC1 — level on the outflow F_out, reverse acting (Kp = -0.034, Ki = -2.1e-4); ∗ TC1 — temperature on the jacket T_jacket (Kp = 5, Ki = 0.02).

The inflow steps from 1.0e-3 to 1.5e-3 kmol/s at t = 1200 s; 3600 s run, 2 s steps. Run it: runCase tutorials/ctrl/ctrl22_reactor_level_and_temperature (it runs under choupoCtrl). Its sibling unsteady06_reactor_fill_and_react fills the same reactor from a heel with no controller.

1. The level loop rejects the inflow step. Plot reactor.level: the peak excursion is 0.010 m (the P-only bound would be dF/ = 0.015 m) and the level is back on 0.50 m at the end (< 2e-6 m). 2. The temperature loop holds 340 K against a colder, larger feed: T dips about 2 K after the step and returns; the jacket temperature (TC1.MV) rises from about 367 K to about 387 K. 3. The loops are coupled through the vessel. The declared UA = 300 W/K is the value with the vessel FULL; the engine scales it with the wetted wall, UA(h) = UA·A_w(h)/A_w(H), A_w = $\pi Dh + \pi D^2/4$ (166.7 W/K at the starting 0.5 m, announced). The reaction heat r·V follows the volume too. 4. The ledger claims mass and energy and closes (~1e-10 or better): both species carry a formation datum, so the vessel takes the canonical energy route, which the run announces.

check_dynamic_cstr_level re-runs this case and holds these numbers.

. . . and 26 more reference values in the case's `expected`.

Category VI: Multi-sector plant showcases

The sectored flowsheet at full size – read them like worked examples. Three of them also carry a plot plan (`system/layoutDict`): `ammonia02_full_plant`, `greenAmmoniaPEQ_baseCase` and `aceticAcid02_plant`. Before moving an item on one, read the section "Plant layout" of the Design Guide (`docs/designGuide.pdf`): siting and wind, separation and hazardous areas, roads and battery limits, pipe racks, storage, the column group, the elevations NPSH fixes, and what the engine checks and what it leaves to you.

ChemicalPlantTutorial

The theory you need. The full multi-sector plant showcase: feed treatment, reaction, separation, utilities – the sectored flowsheet at its largest, run-only (no golden), for reading and dissecting rather than reproducing numbers.

CONCENTRATION

tutorials/plant/ChemicalPlantTutorial/CONCENTRATION

The story: / system/flowsheetDict (SECTOR – COMPOSITE)

Double-effect evaporator (vapour of effect 1 heats effect 2) feeding a crystalliser. Same shape as the plant flowsheetDict, one level down: children + boundary + default feeds + connections.

DRYING

`tutorials/plant/ChemicalPlantTutorial/DRYING`

The story: / system/flowsheetDict (SECTOR – COMPOSITE)

Spray dryer → additional solid drying → cyclone dust separator. The solid powder goes SD → BD → product; the spray-dryer exhaust air (carrying fines) goes SD → CY, which returns clean air + recovered dust.

FERMENTATION

tutorials/plant/ChemicalPlantTutorial/FERMENTATION

The story: / system/flowsheetDict (SECTOR – COMPOSITE with INTERNAL RECYCLE)

Continuous fermentation side-loop of the sugar plant: a slip-stream of fresh juice (Must) is hydrolysed + fermented into ethanol + CO2, the Flash splits the volatiles (EthanolVapour product) from the liquid bottoms, and a Splitter recycles 80 % of the bottoms back to the Mixer so unconverted sucrose gets another shot. Pedagogical purpose:

1. Reaction (Arrhenius first-order in sucrose). 2. Vapour-liquid flash for separation. 3. Tear-stream RECYCLE that the Wegstein/Newton outer loop must iterate to a fixed point.

Must [Mixer] MixedFeed [Fermentor] FermOut [Flash] EthanolVapour Liquid Recycle [Splitter]

Tear stream: Recycle (Splitter output → Mixer input).

MAIN

tutorials/plant/ChemicalPlantTutorial/MAIN

The story: ChemicalPlantTutorial / MAIN / system/flowsheetDict (SECTOR – COMPOSITE)

THE MAIN SECTOR: the plant-level operations that belong to no specialised sector. Here that is one unit, the JuiceSplitter, which takes the single RawJuice header and splits it 2/3 to CONCENTRATION and 1/3 to FERMENTATION.

WHY A LEVEL FOR ONE UNIT (2026-09-05, amended 2026-09-07). Until 09-05 the JuiceSplitter sat at the plant root beside the sectors – a PascalCase unit folder among CAPS folders, breaking the convention this case's own header declares. The rule the plant now teaches: a folder in CAPS is always a level of the plant's geography, and a plant-level unit lives in MAIN/. MAIN/ is THE DOMAIN'S OWN LEVEL, not a sector like the others (the 2026-09-07 amendment), which is why the plant's own inlets and every stream crossing two sectors live there too – a stream's file goes at the lowest level whose subtree contains every endpoint of it. The STATE views repeat the whole geography: 0/ and converged/ both carry MAIN, CONCENTRATION, DRYING, FERMENTATION. A DERIVATIVE view carries only what it has something to say about – design/ has no MAIN/, because a splitter realises no sized item – and that absence is a fact, not a gap to fill. Flat cases are untouched: a case with no sectors has no MAIN either (its units ARE the plant).

aceticAcid02_plant

tutorials/plant/aceticAcid02_plant

What it does: ACETIC ACID FROM CO + METHANOL, rung 2 – the plant around the Gibbs reactor of aceticAcid01: UNIFAC liquid instead of ideal, the reactor gas condensed, the CO recycled against a purge, a degasser, a lights column taking the light by-products (methyl acetate / water / methanol / dimethyl ether) overhead as a declared plant outlet, acetic acid as the bottoms product. One recycle (CO). Still a thermodynamic ceiling: no catalyst, no rate law.

The story: acetic acid from CO + methanol, with its plant. A BASE CASE: it runs, it is NOT optimised, and every number a student would tune is a plain key below (see README section 4).

freshMethanol → [methanolTank] → [methanolPump] → methanolToProcess 1 atm 14 days to 30 bar | +————————————————————-+

+————+ (freshCO arrives by pipeline, not stored) freshCO ———+-→ [M1] -→ [preheater] -→ [reactor] —-→ liquid —+ coRecycle ——+ ^ 460 K gibbsReactor | | | 460 K, 30 bar, v | | approach 10 gas | | | | | [condenser] | | 330 K, 30 bar| | | | | | coGas condensate | | | | | [purgeSplit] +-[M2] | | | | | purge coRecycle v +————————————+ [letdown valve]

[lightsColumn] | | lightsOut acidProduct

[acidTank] -→ acidShipped

ONE recycle: CO, against a 5 % purge. The light by-products leave through the lights column's distillate (a declared outlet, not recycled – a second recycle was built first and cost 7 min 25 s a run for a stream that is 94 % acetic acid). The reactor is the one of aceticAcid01_gibbsReactor.

THE TANKS (DEV.md 4c C87). The methanol is BOUGHT and held in a feed tank before the process takes it; the acid is COOLED and held in a product tank between shipments. Both tanks are 'storageTank' units: the outlet IS the inlet (same F, z, T, P), so they move no process number – what they add is the holdup the plant's working capital rests on, and the equipment the plot plan and an economic analysis must carry. They are SIZED in system/postDict, by a 'storage' entry that LINKS each unit ('unit methanolTank;') and reads its residence time, fill fraction and inlet from it: the stock is declared ONCE, here. CO is NOT stored: it arrives by pipeline at the plant pressure, as a gas no atmospheric tank holds.

Rung 2 after aceticAcid01_gibbsReactor. The same Gibbs reactor, now inside a plant: a methanol feed tank and its pump, a condenser, a CO recycle against a purge, a degasser, a lights column, a product cooler and an acetic acid product tank. It runs (32 s), it converges, and it is deliberately NOT optimised — every number a student would tune is a plain key in system/flowsheetDict. The optimisation is the exercise.

The case is sealed: everything it reads is in its own constant/.

One recycle (CO), closed with Wegstein in 46 iterations. A second recycle (the lights column's distillate back to the reactor) was built first and abandoned: it cost 7 min 25 s a run, and the stream it recycled is 94 % acetic acid. lightsOut is a declared plant outlet.

Two tanks and a product cooler (added 2026-10-18, DEV.md 4c C87): the methanol the plant buys is held in methanolTank before the process takes it, and the acid it makes is cooled in acidCooler and held in acidTank between shipments. The tanks are storageTank units: the outlet IS the inlet, so they move no process number; what they add is the inventory and the equipment (section 8). The cooler is a phaseChanger against the plant's cooling water: the acid leaves the column at its bubble point at 1.5 bar, about 404 K – 13 K above its normal boiling point (391.05 K) – and an atmospheric tank cannot hold a liquid hotter than it boils. The CO is not stored: it arrives by pipeline at the plant pressure.

∗ Reactor: the Gibbs reactor of rung 1 — equilibrium at 460 K, 30 bar, 10 K approach. No catalyst, no rate. Its liquid is ideal by construction (elementPotential: gas plus one ideal condensable); the 10 K barely moves the main product (see rung 1). ∗ Separations: UNIFAC, which is predictive — the catalogue has no regressed pair for most of this system. Every activity coefficient is an estimate from structure. ∗ Vapour: ideal gas. Acetic acid is largely dimerised in real vapour. The engine models that dimer only on its REACTIVE-equilibrium path (a vapourDimerisation block on the acid's gas-liquid chemistry record; see tutorials/steady/flash/flash12_nh3_acetic_ethanol_reactive and flash13); a gamma-phi package like this one (UNIFAC liquid, ideal-gas vapour) has no vapour-association fugacity model, so this case does not use

it and the condenser and degasser splits are indicative. ∗ CO has no UNIFAC group, so it sits outside the activity model (approximations block, announced as a ∗substitution∗ on every run). ∗ Battery limits: the methanol arrives as a liquid at 1 atm into its feed tank, and methanolPump (efficiency 0.65, assumed) lifts it to 30 bar. The CO arrives by pipeline, declared at 30 bar; no CO compressor is modelled. ∗ M1 is a mixer AND a heat exchanger in one box. It merges a liquid (the pumped methanol) with two gases at a DECLARED 320 K, because a gas + liquid merge has no well-posed adiabatic temperature, and it publishes the duty that temperature implies (Q_kW, priced like every other duty; about +81 kW, allocated to LP steam). Without that duty the plant's first law was open by about 80 kW (DEV.md 4c C71, C74). The mixer does not flash: its outlet carries the dominant label (vapour), and the energy report says on every run that mixedFeed cannot hold that label at 320 K and 30 bar (the methanol's partial pressure is far above its vapour pressure there). That label decides how the methanol's latent heat is SHARED between M1 and the preheater; the plant's total heat does not depend on it, the utility bill does. An exercise: put an isothermal flash after M1 and see where the duty goes. ∗ The pump's own energy balance is announced as FAILED on every run (dH 1.76 kW against 5.04 kW of shaft work, 35 % = 1 - eta). It is the engine's, not the case's: the liquid enthalpy of this package carries no pressure term (measured here – moving 0/freshMethanol from 30 bar to 1 atm left the plant's feed enthalpy unchanged to the last digit), so the 3.28 kW of useful work v·dP the pump puts into the liquid is invisible to the energy report, and only its 1.76 kW of dissipation shows as a temperature rise. tutorials/steady/rotating/pump01_water shows the same 65 % gap. ∗ Data: dimethyl ether is reviewStatus interim with a Joback formation enthalpy (see rung 1); it is nil in every stream here. ∗ Antoine ranges are exceeded at 460 K (dozens of announcements per run) and the column prints [distillate] WARNING lines (47 in the base case): the distillate's bubble point does not converge because CO and dimethyl ether have no real saturation curve at those temperatures, so the distillate temperature is reported at the top tray. Neither changes a flow.

Decision variables (all in system/flowsheetDict unless noted):

acetonePlant

tutorials/plant/acetonePlant

What it does: Acetone from 2-propanol: Luyben's Figure 1 closed, with the IPA recycle

The story: ACETONE FROM 2-PROPANOL, THE CLOSED FLOWSHEET

W. L. Luyben, "Design and Control of the Acetone Process via Dehydrogenation of 2-Propanol", Ind. Eng. Chem. Res. 50 (2011) 1206-1218, DOI 10.1021/ie901923a – his Figure 1 (the Turton base case), end to end:

fresh feed + IPA recycle → vaporiser → reactor → separator → absorber (offgas washed) → C1 → acetone product → C2 → water product → IPA RECYCLE (tear)

This is the case the six preceding ones were built to make possible. Each of them isolates one unit on Luyben's OWN published inlet, so that whatever it gets wrong is that unit and its thermodynamics. Here nothing is published except the fresh feed: every internal stream is the plant's own answer, and the errors compose.

WHAT THIS CASE CLAIMS, AND WHAT IT DOES NOT. It claims to be Luyben's TOPOLOGY and Luyben's EQUIPMENT SPECIFICATIONS solved on the thermodynamics Choupo actually has. It does NOT claim to reproduce his stream table – the siblings measured, in advance, exactly why it cannot, and the gap between his table and this one is the deliverable rather than a defect to be closed:

acetone01: UNIFAC puts the IPA/water azeotrope at x 0.590 against his 0.673, and the lake-estimated isopropanol boils 4.5 K high. acetone04: UNIFAC INVENTS an acetone/water azeotrope at x 0.978 where his UNIQUAC has none – 0.044 K deep, and decisive. acetone06: so C1 caps at 97.3 mol % acetone against his 99.9 % spec. acetone07: so C2's recycle caps at x_IPA 0.580 against his 0.650, and 11.6 % of the isopropanol entering it leaves in the water product.

Both column ceilings were WRITTEN DOWN BEFORE the columns existed and are pinned by check_azeotrope_ceiling. This case is where they stop being two separate findings and become one plant.

DEPARTURES FROM HIS FIGURE 1, each argued rather than absorbed

(a) NO HYDROGEN IN THE COLUMNS. His C1 has a partial condenser and a vent (0.0465 kmol/h, carrying 0.0130 kmol/h H2 and 0.0335 kmol/h acetone); Choupo's column has a total condenser and no vapour distillate. A permanent gas fed to a total condenser is asked to leave as a liquid, and the engine rightly refuses (hydrogen has no liquid heat capacity at 330 K). So the separator's LIQUID goes to C1 and the hydrogen leaves with the offgas, i.e. the columns are modelled downstream of his vent. Cost, stated: the 0.0335 kmol/h of acetone his vent loses is not lost here, which flatters this plant's acetone recovery by 0.10 %.

(b) THE SEPARATOR DOES THE COOLING. An isothermal flash at 318 K computes the duty to bring its feed there, so this one unit stands for his HX1 plus his separator and its Q is directly comparable to his 0.8993 MW. A separate 'heater' was tried in acetone03 and refused, correctly: Choupo's heater takes a DUTY and reports the temperature, because a heater with a specified outlet temperature is a design specification.

(c) THE SEPARATOR PRESSURE IS ARGUED, NOT FITTED. Luyben states 1.5 atm for the absorber gas, which is downstream; there is no compressor between reactor and separator and pressure only falls, so the separator sits at the reactor's 2.6 atm. acetone03 records the sweep that would have tempted a fitted value and why it was refused.

(d) THE ABSORBER'S SECOND OUTLET REJOINS C1's FEED, as in his Figure 1 (his F1 of 72.85 kmol/h is the flash liquid AFTER the absorber bottoms of 20.05 kmol/h rejoin it).

(e) NO VENT/PURGE ON THE RECYCLE LOOP. Luyben has none either – the loop closes through C2's overhead and nothing else – so this is his structure, not a simplification. It does mean any component

that both enters and cannot leave would accumulate without bound; here water leaves in three places and isopropanol in two, so the loop is closed and bounded.

Acetone from 2-propanol: the flowsheet of W. L. Luyben, ∗Design and Control of the Acetone Process via Dehydrogenation of 2-Propanol∗, Ind. Eng. Chem. Res. 50 (2011) 1206, his Figure 1 end to end — fresh feed and isopropanol recycle into a mixer, a vaporiser to 389 K, a conversion reactor at 623 K and 90 % per-pass conversion, a separator chilled to 318 K, an absorber washing the offgas with 20 kmol/h of water, a vent, and two columns: C1 (66 stages, feed 54, R 2.78) making the acetone product and C2 (19 stages, feed 16, R 0.849) returning the isopropanol. Nine units, one cycle, and the cycle is declared: system/solverDict cuts it at ipaRecycle and closes it with Wegstein.

Everything on the first path so far arrives here at once — an equilibrium, a model choice, a many-stage unit, a method that has to be chosen, a reaction, a graph, a recycle. And one thing more, which is why this case is last.

It does not reproduce Luyben's stream table, and that is the deliverable. Seven sibling cases (acetone01 to acetone07) each measured ONE unit on Luyben's own published inlet ∗before∗ this plant existed, so every difference below was predicted rather than discovered. Nothing was tuned to close a gap.

That first row is 85 % of his acetone, and the case's own CLAUDE.md records the product at 0.9727 mole fraction acetone against his 0.999 spec.

1. The error has an address, and it was written down first. UNIFAC invents an acetone/water azeotrope at x 0.978 where Luyben's UNIQUAC has none (acetone04), which caps C1; UNIFAC also misplaces the real isopropanol/water azeotrope at x 0.590 against 0.673 (acetone01), which caps C2. Both ceilings were measured on isolated units before either column was built, and the golden shows them arriving: C2 x_D_LK is 0.499124702623, and a wetter recycle carries less isopropanol, which makes less acetone, which is the production figure in the table. A plant whose disagreement you can name unit by unit is worth more than one that agrees for reasons nobody checked. 2. Two thermodynamic worlds, and the boundary is priced. Handed the plant's global UNIFAC package the absorber REFUSES by name: it solves Kremser, Kremser reads Henry's law, and an activity model carries no answer it can use. So that unit alone carries an inline thermo {} block — water the solvent on the pure-liquid rung, acetone the solute on the Henry rung — declared where the model boundary is and announced when the run crosses it. The block is inline in system/flowsheetDict rather than in a file of its own for exactly that reason. The model-boundary ledger then prices the crossing independently and writes its verdict to reports/balances/energyBalance_byUnit.csv: raw imbalance -11.2496 kW, declared boundary step 0.0000 kW, remaining -11.2496 kW, and in the report's own words ∗the step is NOT credited∗. Read the report for it, not the expected file: that row is held by check_model_boundary_ledger, and this case's golden carries no row kind that can read it. Changing the liquid activity model changes K-values, not the enthalpy datum, so there is nothing to credit at this boundary — and the residual that remains belongs to the absorber's own lumped-Cp energy model, which the case's CLAUDE.md traces and does not excuse. 3. A declared approximation was not locally contained. constant/thermoPhysPropDict authorises hydrogen to run at gamma = 1, by name and with its reason: no UNIFAC group for hydrogen exists, and inventing one would be fabrication. The stated stake was small — a liquid mole fraction of 2e-4. Three units downstream that residue diverges the rigorous MESH in C1, which is why there is a vent flash in this flowsheet that is not in his Figure 1. It is an explicit unit, not a deletion, so what leaves with the hydrogen is computed: the golden pins vent V_over_F at 0.00201400452928. This is the clearest thing the plant has to teach. 4. The tear seed is a guess, and the plant walks away from it. 0/ here is authored and committed, one file per stream, and 0/ipaRecycle is seeded with Luyben's own published recycle composition — 3.822 kmol/h isopropanol, 0.004116 acetone, 2.053884 water in 5.88 kmol/h, which is x 0.650 and 0.0007 exactly as his table reports. The converged answer is x 0.4991. The seed is the author's, visible, and owned; the solver moved off it and said so. (Where a case ships no 0/, bin/choupo-init0 materialises one from the authored inlets and the tear seed.) 5. A specification that survives a recycle is not the same as a rate. C1 asks for distillateRecovery { component acetone; fraction 0.97; } rather than Luyben's 32.25 kmol/h, because the acetone reaching C1 shrinks on every turn of the loop: a rate that is feasible on the first pass is infeasible on the third, and the flowsheet would then fail on arithmetic instead of physics. The golden confirms the spec was met — C1 recovery_acetone 0.969999992418 — in three outer searches. C2 keeps his rate, because its feed is not starved the same way. 6. The plant still closes. Global mass closure at 100 %, and the plant-boundary first law pinned at H_feeds_kW -5862.58875482, Q_boundary_kW 632.174396749, H_products_kW -5236.98782168, a residual of 6.57346360643 kW. A disagreement with a paper and a violation of conservation are different things, and this case is careful to be only the first.

Read the case's own CLAUDE.md first: it carries the full comparison against Luyben's Figure 1, the five traced sources of error, and a ∗Pending∗ list that names the one change which would move every row — fitted UNIQUAC or NRTL pairs for the three binaries, which is the honest way to close the gap and is a

curation job rather than a code job. The build history is docs/design/acetone-plant-closure-state.md; the programme is docs/design/acetone-ipa-reference-case.md.

ammonia02_full_plant

tutorials/plant/ammonia02_full_plant

What it does: Full-scale ammonia SYNTHESIS LOOP at 200 bar (~59 t/h NH3, 1400 t/day) – a synthesis-loop fundamental, not a whole ammonia plant: the syngas arrives as a declared 25 bar makeup and its production is not modelled. Explicit syngas + recycle COMPRESSORS, feed-effluent HEAT EXCHANGER, ADIABATIC converter (the reaction heats itself – exothermic), water cooler + refrigerated separator, product let-down, and the recycle + purge. SRK fugacity throughout; dissolved H2/N2 by measured Henry constants (Wiebe 1934, Larson-Black 1925 via IUPAC SDS 5/6).

The story: the complete Haber-Bosch plant, ~59 t/h NH3

makeup 25 bar [makeupComp 25→200] recycle [recycleComp] [mixer] mixed (cool) cold side [FEHE] hot effluent (heat recovery) preheatedFeed (~683 K) [converter] gibbsReactor mode ADIABATIC N2+3H2<→2NH3 exothermic → self-heats to ~840 K hotEffluent hot side of FEHE → cooledEffluent [waterCooler] (cooling water) ~310 K [separator] flash 250 K/200 bar (refrig.) rawLiquid unreactedGas [letdown] [purgeSplit] productNH3 gas purge recycle (tear)

THE REACTOR HEAT. N2+3H2→2NH3 is EXOTHERMIC – there is NO external reactor heating. The converter runs ADIABATIC: the exotherm raises the gas T (feed 683 K in, 840 K out), and the feed-effluent exchanger (FEHE) recovers that heat to preheat the incoming feed to catalyst light-off. Self-sustaining once lit. The compressors set the 200-bar synthesis pressure; the water cooler (cooling-water utility) + refrigerated flash condense the NH3. Every machine is explicit and its duty/work is reported.

CAPACITY ~59 t/h NH3 (~1400 t/day) at 98.6% product purity – a world-scale single train.

DISSOLVED GASES BY HENRY'S LAW. H2 and N2 are supercritical at the separator (no physical Psat), so their dissolved amounts follow MEASURED Henry constants (pairs H2-NH3 from Wiebe 1934, N2-NH3 from Larson & Black 1925 as evaluated in IUPAC SDS Vol 5/6), with the SRK vapour fugacity at 200 bar: K = H(T)/(phi_V P). The raw liquid carries ~0.5% H2 + 0.2% N2 – physical, vs the ~13% a Psat extrapolated above Tc used to fake. KNOWN RESIDUAL: Ar has no measured Ar-NH3 Henry pair yet, so its dissolved ~1% is a Raoult-extrapolation artefact (~7x over by analogy with N2) – the product's main impurity is overstated.

THE SIMULATION STRATEGY (how you build a plant like this). 1. PICK THE THERMO BY THE PHYSICS, per phase ("the two worlds"): the 200-bar GAS side needs real-gas fugacity → a cubic EoS (SRK) declared once in the package; the reactor folds phi into its equilibrium automatically. The DISSOLVED gases are supercritical solutes in a condensable solvent → the unsymmetric convention (Henry / Krichevsky-Kasarnovsky), NOT Raoult: pair files H2-NH3 + N2-NH3 fitted to measured solubility, 'solvent NH3;' in the package, 'role solute;' overlays on H2/N2 in this case's constant/. 2. TEAR THE LOOP WHERE INFORMATION FLOWS BACKWARD: one MASS tear (recycle, guessed then Newton-converged) and one ENERGY tear (hotEffluent – the FEHE preheats the feed with the reactor's own product heat, so the converter's outlet is needed upstream of the converter). Both declared in solverDict tearStreams; the solver announces every iteration. 3. LET THE EXOTHERM DO THE HEATING: the converter is ADIABATIC (mode adiabatic; T is a guess, not a spec) – the reaction self-heats 683 → 840 K and the FEHE recycles that heat to light off the feed. No phantom reactor heater exists anywhere. 4. MAKE EVERY MACHINE EXPLICIT so it can be SIZED AND COSTED: compressors by shaft power, exchangers by area, the converter + drums by vessel design bases (space velocity / residence time) in system/postDict → Turton costs → the DCF economics in constant/economics. Every unit operation carries its own sizing – the doctrine. 5. VALIDATE AGAINST MEASUREMENT AT EVERY JOINT: the reactor equilibrium against the ideal-vs-SRK shift (gibbs10), the dissolved gas against Wiebe 1934 / Larson-Black 1925 (x_H2 at 400 atm: 0.0287 computed vs 0.0282 measured), the balances against 100% element closure.

HONEST SIMPLIFICATIONS. (1) The converter is a SINGLE adiabatic bed, so it runs hotter (~567 C) than a real multi-bed converter with interbed quench cooling (which stays near the 400-500 C equilibrium sweet spot for more NH3 per pass). (2) The makeup compressor is one stage (real: multi-stage with intercooling), so its discharge is hot. (3) The let-down gas and the loop pressure drops are as in ammonia01. (4) 'water' is in the package ONLY as the cooling-water utility fluid (it is not a reaction species).

CONVERTER

tutorials/plant/greenAmmonia03_basicDesign/CONVERTER

The story: THE MULTIBED CONVERTER – ONE SECTOR, ONE PRESSURE VESSEL (DEV.md 4c C69).

Three adiabatic catalyst beds with an interbed cooler after each of the first two. The flowsheet still computes FIVE blocks – each bed and each cooler is a calculation of its own – but they are built as ONE piece of equipment: the beds sit in a basket inside a single pressure shell, with the interbed exchange inside the same shell. That is a fact about the EQUIPMENT, so it is said where the equipment is sized: system/postDict's 'converterShell' entry names this sector, stacks its members' geometries into one shell at the loop's design pressure, and the beds' own shells become internal baskets that are not priced twice.

WHERE THE ARRANGEMENT WAS READ (2026-10-12), and what was not: The M. W. Kellogg Company, "Ammonia synthesis converter", EP 0 254 936 A2 (1988), read on the EPO publication server: "the vertical converter is contained within cylindrical pressure shell 1", three axial-flow catalyst beds "within the cylindrical inner shell", and interbed cooling "supplied entirely by the single indirect heat exchanger" inside it – ONE interbed exchanger, not two. Topsoe, "Ammonia converter baskets S-300" (product page, read): three catalyst beds, radial flow, a BASKET installed in a pressure shell, in one version with an integral feed-effluent exchanger after the third bed. The page does not describe its interbed exchangers. Neither source describes TWO interbed coolers raising steam, as these two do; that arrangement is the base case's, and the one-shell grouping is the sources' general construction applied to it.

The stream names are the plant's, unchanged: the sector's inlet is the FEHE's preheated feed, its outlet the hot effluent the FEHE cools.

hda

tutorials/plant/hda

What it does: HDA plant – toluene + H2 → benzene + CH4. A single FLAT flowsheet with two plant-level recycles (an H2 gas loop and an unreacted-toluene liquid loop); cross-sector tears are unsupported, so it has no sectors. Furnace lumped into the isothermal reactor; the plant runs on SRK (phi-phi, kij = 0) because H2 and CH4 are above their critical temperatures, where a Raoult K has no vapour pressure to read; the shortcut column alone keeps the ideal package (see the flowsheetDict).

`lithiumBrinePlant`

`tutorials/plant/lithiumBrinePlant`

What it does: lithiumBrinePlant – THE reference case: a SECTORED lithium-carbonate plant from salar brine, WIRED into one solver. Five SECTORS, each a thermo WORLD of its own – BRINE (electrolyte/Pitzer), EXTRACTION (gamma-gamma NRTL LLE), CARBONATION (Li2CO3 retrograde solubility), HOTAIR (Gibbs combustion), FINISHING (drying + cyclone) – connected sector to sector, each sector declaring its own propertyPackage (its world) on the global component set, with optional per-unit thermo overrides where a single unit needs a different world. The proof that a plant and its sectors run as one: sectors are composite boxes, streams flow between them, model boundaries audited.

The story: Five REAL sectors. Streams are named physical graph edges. Sector names are subdomains; unit operations live inside each sector.

polycaprolactonePlant

The theory you need. Ring-opening polymerisation plant: monomer to polycaprolactone with step-growth KPIs (Carothers, Flory) on the PFR, polymer properties from group contribution on the repeat unit.

properties

tutorials/plant/polycaprolactonePlant/properties

What it does: Close the loop: ESTIMATE the PCL repeat-unit glass transition Tg by the Yang 2020 group-contribution scheme — the plant gives Mn/PDI, this gives the physical property from the SAME repeat unit -[O-(CH2)5-CO]-

The story: pclProperties – CLOSE THE LOOP: process → molar mass → physical property.

The plant (../) gave you the chain statistics from the KINETICS: Mn, Mw, PDI on the polycaprolactone it makes. Here you ESTIMATE the polymer's PHYSICAL PROPERTIES from the SAME repeat unit -[O-(CH2)5-CO]- by group contribution — the bridge from "how big are the chains" to "how does the material behave".

TWO estimators, two properties, on the repeat unit pclRepeat (M0 = 114.14):

(A) Tg, the GLASS-TRANSITION temperature — Yang 2020 (run below). Repeat unit -[O-(CH2)5-CO]- decomposes into Yang main-chain groups: O x1 : MW 16 Yg -14.718 CH2 x5 : MW 14 Yg 4.026 (each) CO x1 : MW 28 Yg 4.370

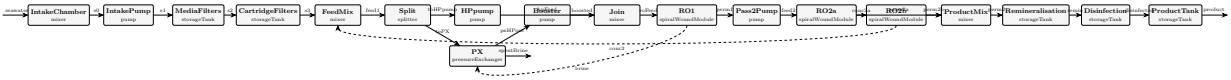
M0 = 16 + 5∗14 + 28 = 114 g/mol (matches the reactor M0!) Yg(inf) = -14.718 + 5∗4.026 + 4.370 = 9.782 (1e3 g.K/mol) Tg(inf) = 9.782e3 / 114 ~ 86 K (the additive estimate) (Measured PCL Tg ~ 213 K / -60 C; an additive main-chain scheme is weak for a flexible aliphatic polyester — the model tells the truth about itself, which IS the lesson. See the console's per-cent error vs the anchor.)

(B) DENSITY — Van Krevelen (Bondi Vw). NOT runnable on PCL with the shipped data: the Slice-1 Van Krevelen set ships only hydrocarbon + chloro groups (CH3 CH2 CH C ACH AC CHCl CH2Cl); it has NO ester -O- / -CO- group, so the repeat unit -[O-(CH2)5-CO]- cannot be decomposed. Running it would HARD- ERROR with "unknown polymer group 'O'" — the estimator refuses to invent a value (no silent zero). The honest path: density needs the ester groups curated into data/standards/-parameters/vanKrevelen.dat first. The worked Van Krevelen DENSITY example lives in tutorials/props/estimate/vanKrevelen01_polystyrene_density (a pure- hydrocarbon repeat unit the Slice-1 set CAN do).

This is the same M0 = 114.14 the reactor's polymer{} block used for Mn = M0/(1-p) — one repeat-unit mass, two places (process AND property).

A choupoProps sub-case of [../](..) (the polycaprolactone plant). The plant gives you the chain statistics from the kinetics (Mn / Mw / PDI); here you estimate the polymer's physical property — the glass transition Tg — from the same repeat unit -[O-(CH2)5-CO]- (M0 = 114.14, the exact number the reactor used for Mn = M0/(1-p)).

∗ Tg via Yang 2020 (CC-BY) — runnable. Tg(inf) = 85.8 K; the console prints the -59.7 % deviation from the measured ~213 K (an honest limit of an additive scheme on a flexible aliphatic polyester). M0 = 114 is goldened (an exact mass-balance fact); Tg is shown but not goldened as validated physics. ∗ Density via Van Krevelen — ∗not∗ runnable on PCL with the shipped data (the Slice-1 group set has no ester -O-/-CO- group, so it would hard-error rather than invent a value). See the full explanation and the runnable hydrocarbon example linked from the parent ../README.md.



The full teaching narrative lives in the parent README. See system/propsDict for the exact group decomposition and the estimator invocation.

What to expect (golden-locked):

swro01_campoDalias

tutorials/plant/swro01_campoDalias

What it does: Campo de Dalias two-pass seawater desalination plant from a manufacturer's public case study: pretreatment, first pass with pressure-exchanger energy recovery, second pass with the concentrate recycled, boron, post-treatment placeholders, and a plot plan up to the fence

The story: A TWO-PASS SEAWATER DESALINATION PLANT FROM A MANUFACTURER'S PUBLIC CASE STUDY (DEV.md 4c C194).

SOURCE. Toray Industries, "Seawater Desalination Using Toray's RO Membranes to Support a Thriving Agricultural Economy" (Campo de Dalias Desalination Plant, Almeria), MC-CS-CAMPODEDALIAS-1910, 2019: two pages, a MANUFACTURER'S document about its own membranes. Every performance figure in it is Toray's claim "based on manufacturer's test conditions"; none is a measurement of this case. It gives: an open intake by a 1.6 km subsea pipeline; pretreatment by 40 dual-media filters (glass-fibre-reinforced polyester) then 5-micron cartridges (99.6 % particulate removal); a two-pass reverse osmosis of six skids each, the first pass TM820E-400 seawater elements (skid 233 vessels of 7 elements, "233 (7M)"; 37 m2, 28.3 m3/d, 99.75 % NaCl and 91 % boron at pH 8; "47.2 % system recovery"), the second pass TM720C-430 brackish elements (54:18 vessels of 7 elements; 40 m2, 33.3 m3/d, 99.2 % NaCl and 95 % boron at pH 10; "84-90 %" recovery); the second pass's concentrate recycled to the first; an isobaric energy-recovery system of 95 % efficiency (DWEER); post-treatment by remineralisation and disinfection; 98 664 m3/day; the feed analysis (its Table 2); a permeate target of TDS $<$ 400 mg/L and boron $<$ 0.5 mg/L. NOT in it: a site plan, vessel and pump counts beyond the skid designs, pump sizes, energy per m3, costs, the temperature of operation (14-23 C is the feed's range).

WHAT THIS CASE TAKES FROM IT, AND WHAT IT ADDS. From the document (origin literature): the 98 664 m3/day; the six skids and their vessel counts (1398 vessels in the first pass, 324 + 108 in the second, 7 elements each); the elements' areas, flows and rejections; the 47.2 % first-pass recovery and the second pass's 84-90 % (87 % chosen); the 95 % energy-recovery efficiency; the recycle; the feed analysis. The document's two internal figures for the product differ slightly (98 664 m3/day against 6 skids x 16 442 = 98 652): the case uses 98 664. ASSUMED by the case, each with its reason where it stands: the test conditions of the manufacturer's figures; the membranes' water permeances (derived from them); the elements' geometry; the temperature (25 C, 2 K above the document's feed range – the module has no temperature correction of A_w); pump efficiencies; the device's mixing and leakage; every hold time and tank; the whole plot plan. NOT MODELLED: the particulate removal of the filters (no solids), the filters' own pressure drop, the pH and the caustic dosing between the passes, the remineralisation and disinfection chemistry, the real device's piston hydraulics, fouling and the elements' ageing.

THE SALTS ARE ONE LUMPED SOLUTE. The document's Table 2 lists twelve ions (TDS 38 697 mg/L). The module's rated-test inversion needs a salt, not ions, so the ions are replaced by NaCl at the SAME OSMOTIC PRESSURE: the ions' 1235.9 mmol/L give 617.9 mmol/L NaCl = 36.11 g/L, against the 38 697 mg/L of actual TDS (the lump weighs 6.7 % less than the ions; the permeate TDS quoted below, as NaCl, reads about 7 % lower than a real TDS). Boron (5.3 mg/L as B) is a second lumped solute.

THE FIGURES THE DOCUMENT CALLS "FEED PRESSURE" ARE THE TEST PRESSURES, AND THE PLANT'S ARE SOLVED. Table 1 prints 5.52 MPa (800 psi) and 1.03 MPa (150 psi) beside the elements' flow and rejection, which are test figures. The case takes them as the rated tests' pressures. They cannot be the plant's: a 47.2 % recovery of this seawater leaves a concentrate at 63.5 g/L NaCl-equivalent (about 53 bar of osmotic pressure), which 55.2 bar cannot push past; the first pass here needs 58.6 bar (HP pump and booster discharge) for 47.2 %. The second pass runs at 10.74 bar, not 10.3, which puts its recovery at 87 % (the document's 84-90 %) with the first pass's permeate: at 10.3 bar the same array recovers 94.8 %.

WHAT THE RUN SAYS (2026-11-02, boron split by the pH, C198; the golden is the authority): product 4111.2 m3/h = 98 668.7 m3/day (the document's 98 664) intake 9461.3 m3/h; recovery of the intake 43.5 % first pass 47.20 % recovery (the document's 47.2 %), 13.05 LMH average flux on 362 082 m2, feed 10 011 m3/h at 58.59 bar, brine 63.5 g/L NaCl-eq at 57.9 bar, permeate 109.6 mg/L NaCl-eq, boron 0.457 mg/L

second pass 87.0 % recovery, 33.99 LMH on 120 960 m2 (the element's rated 34.7), concentrate 614 m3/h at 0.83 g/L, boron 3.2 mg/L, recycled to the first product 1.9 mg/L NaCl-eq (the document's target < 400 mg/L TDS), boron 0.043 mg/L (< 0.5) energy recovery flows balanced to 1e-5; 54.1 bar recovered on 5209 m3/h, 7.76 MW hydraulic; the feed's salinity up 1.8 % pump shaft powers HP pump 9185 kW, booster 437 kW, second-pass pump 1604 kW, intake 326 kW: 11 552 kW, i.e. 2.81 kWh per m3 of product (shaft only: no motor losses, no pretreatment or post-treatment loads, no product delivery)

BORON IS TWO SPECIES SPLIT BY THE pH (DEV.md 4c C198, Stage 1). Boron is the reason for the second pass and for the caustic between the passes: boric acid (neutral, small enough to pass a seawater membrane) is converted at pH 10 into borate (an anion, rejected). Each module declares 'aqueousSplit {}': the apparent boron is carried as H3BO3 and BOH4, the base fraction alpha = 1/(1 + 10^(pKa - pH)) is asked of the PACKAGE (the curated constant data/standards/chemistry/BOH4-formation.dat, pKa 9.24 with its van't Hoff enthalpy, and this case's declared aqueous activity model, Davies, for gamma and a_w) at the module inlet's bulk and the DECLARED pH, and each form has its own intrinsic rejection. Alpha is 0.108 at the first pass (pH 8.2, I = 0.59 mol/kg) and 0.858 at the second (pH 10). THE PERMEANCES come from the sheet's rated tests: ONE boron test per element (91 % at pH 8; 95 % at pH 10, 'boronRef' in the two records) is inverted through the module's own film and, at the test's own alpha, determines the ACID's rejection; the BASE's is a DECLARED ASSUMPTION (the element's own NaCl rejection: an anion rejected like the salt) because one test cannot identify two permeances. TWO tests of one element at two pH would give both ('rejection { tests (id1 id2) }'; the gate runs that form on a fixture), and the engine refuses a single test offered as two or two at the same pH. The result is R_acid 0.932 and R_base 0.998 for the first-pass element, 0.790 and 0.994 for the second-pass one. THE LIMITS, announced on every run: THE pH IS A DECLARED LABEL of each module (8.2, Table 2; 10, Table 1), not a state – no stream carries a pH, and the caustic dosing that would set the second pass's pH is NOT a unit (Stage 2); the split is FROZEN at the inlet's pH along the channel; both forms share the one film coefficient; Davies is outside its own ~0.5 mol/kg band at seawater strength, so alpha at the first pass is indicative (the apparent pKa it gives, 9.12, is NOT Dickson's conditional seawater constant, 8.60 on the total scale – the comparison is printed by the gate, never tuned). What the case now shows: lower the second pass's declared pH from 10 to 9 and the product's boron rises from 0.04 to 0.14 mg/L, as alpha predicts. A finding about the probe: the boron test is water plus 5 ppm boron at the test's pressure, with no osmotic pressure to oppose it, so it runs at 19 % recovery instead of the test's 8-15 %; the derived effective rejection (0.9357, 0.9642) is that of the probe. And boron is a solute of the van't Hoff osmotic pressure ('dissociation 1'): the second pass's feed is so dilute that boron is about 1 % of its osmotic pressure, so the product moved by 0.004 % when boron's rejection changed from the lumped to the split form (the NaCl-side rows of the golden moved for that reason alone).

THE LOOP IS A KNIFE-EDGE, AND 0/ IS A CONVERGED STATE. The exchanger returns 99 % of the brine's volume to the membrane feed, so the first pass is a loop of gain near one (membrane27 shows it), and the second pass's concentrate is a second tear. A cold start from a rough guess converges, with this Wegstein, to a SPURIOUS fixed point (all water circulating, no permeate); 0/ therefore holds the converged state of a previous run and the case restarts from it in two iterations. Changing a pressure or a flow moves the answer: re-seed from converged/ or tune the split fraction (0.4791) to balance the exchanger. The intake flow, the split, the two pass pressures and the first-pass pressure were solved together for the product, 47.2 %, 87 % and a balanced exchanger.

SIX TRAINS (DEV.md 4c C199). The document's six skids are six identical trains in parallel, so this flowsheet carries their SUM ('vessels 1398' is 6 x 233, and the pumps and the exchanger carry six times a train's flow); the physics is the same and is solved once. The sizing is per train: system/postDict declares 'trains { count 6; }' and yields train1 .. train6 for each pump, exchanger array and vessel bank.

THE PLOT PLAN (system/layoutDict) is Choupo's design of a plant of this scale up to the fence, NOT the real site: the document gives no site plan.

The question. Two pages from a membrane maker describe a 98 664 m3/day two-pass seawater plant in Almeria: pretreatment, a first pass at 47.2 % recovery with isobaric energy recovery, a second pass that polishes the boron, the second pass's concentrate recycled to the first. What does it take to turn those two pages into a simulated plant – and what do the pages not say?

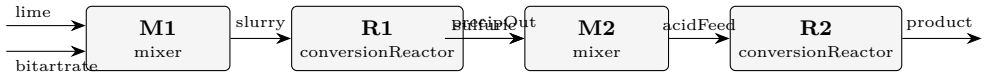
What the case is. system/flowsheetDict (read its header first): intake, pretreatment placeholders, a high-pressure pump, a pressure exchanger and a booster feeding 1398 vessels of TM820E-400 elements (the first pass), a second pass of 324 + 108 vessels of TM720C-430 on the first pass's permeate, the concentrate recycled, post-treatment placeholders and a product store. The two Toray element records are CASE-LOCAL

(constant/assets/): the document's figures are the manufacturer's claim, and what it does not state (the test conditions, the water permeances, the geometry) is declared assumed or estimated. system/layoutDict is Choupo's plot plan of a plant of this scale up to the fence – NOT the real site.

The answer (2026-11-02; expected is the authority). Product 4111 m3/h = 98 668.7 m3/day; first pass 47.20 %, second 87.0 %; 2.0 mg/L NaCl-equivalent and 0.043 mg/L boron in the product; 2.81 kWh/m3 of pump shaft work.

Boron (DEV.md 4c C198, Stage 1). Boron is carried as boric acid and borate, split by the pH against the acid's curated pKa through the package; each module declares its pH (8.2 for the first pass, Table 2; 10 for the second, Table 1 – the caustic dosing is not modelled). Lower the second pass's pH to 9 and the product's boron rises; the sheet's one test per element fixes the acid and the borate is assumed rejected like the salt (declared, announced).

Six trains, one building (DEV.md 4c C199). The case study says six skids of 16 442 m3/day, and an industrial SWRO plant is built so: identical trains, each with its own high-pressure pump, its own array of pressure exchangers and its own vessel racks. The flowsheet is solved ONCE at plant flow (six identical trains in parallel carry six times a train's flow) and the SIZING is done per train: system/postDict declares trains { count 6; ... } and the pumps, the exchanger arrays and the vessel banks yield items train1 .. train6 with their per-train numbers beside the plant's. A pump is rated by the largest machine one make builds (Sulzer MSD-RO, 1600 m3/h: one per train at 50 % load, plus a declared spare), the exchanger array is 6 devices of the Energy Recovery PX Q650 window per train under its 83 bar limit, and each pass's vessels stand in racks (233 vessels of 7.64 m in 5 racks of four tiers, the loading clearance of one vessel length at the east end of each bank). The 42 items stand in the four rooms of one reverse-osmosis building in system/layoutDict. What the open sources did not give – the rack pitch, the aisle, the loading clearance – is declared assumed and says so.



What a student should notice. 1. The document's "feed pressure" figures (5.52 and 1.03 MPa) are TEST pressures: 47.2 % recovery of this seawater needs 58.6 bar, and the second pass needs 10.74 bar for 87 %. The header shows the arithmetic. 2. Boron is where the engine stops. The module does not couple the pH to the transport, so boron is one lumped solute with a constant rejection read from the manufacturer's two pH-labelled tests; the gate pins that relabelling the pH moves nothing. The follow-up is named in the header and in docs/design/a-desalination-plant-from-a-case-study.md. 3. The loop through the exchanger is a knife-edge with a spurious solution; 0/ is a converged state for that reason. 4. The plot plan announces six findings (five water tanks with no bund, one entrance) and leaves them. 5. The pump count is ceil(flow per train / the largest pump): with 6 trains it is 1 per train; with ONE train the same high-pressure flow (4791 m3/h) would need 3 pumps in parallel (declare installed { count 3; }; the sizer says so when you do not).

What to expect (golden-locked):

tartaricAcid

tutorials/plant/tartaricAcid

What it does: Tartaric-acid plant (wine route): lime precipitation of calcium tartrate, then sulfuric acidulation to tartaric acid + gypsum. Molecular reactors; the solution chemistry sub-study is tutorials/props/electrolyte/-tartaricAcid_acidulation. HONEST LIMITS: H2SO4 declared nonvolatile by case overlay (Psat ~1e-5 Pa at process T); precipitates ride as nonvolatile solutes with NO rigorous solid-liquid separation; reactor duties honestly UNAVAILABLE (species without ideal-gas Cp – a named gap, never a fake zero).
